They even prefer unusual names, as psychologist Jean Twenge noticed while seeking a name for her first child. Over time, the most common American names listed by year on the U.S. Social Security baby names website were becoming less desirable. When she and her colleagues (2010) analyzed the first names of 325 million American babies born between

1880 and 2007, they confirmed this trend. As **FIGURE 59.3** illustrates, the percentage of boys and girls given one of the 10 most common names for their birth year has plunged, especially in recent years. (No wonder my parents, who welcomed my arrival in a less individualist age, gave me such a common first name.)

The individualist-collectivist divide appeared in reactions to medals received during the 2000 and 2002 Olympic games. U.S. gold medal winners and the U.S. media covering them attributed the achievements mostly to the athletes themselves (Markus et al., 2006). “I think I just stayed focused,” explained swimming gold medalist Misty Hyman. “It was time to show the world what I could do. I am just glad I was able to do it.” Japan’s gold medalist in the women’s marathon, Naoko Takahashi, had a different explanation: “Here is the best coach in the world, the best

manager in the world, and all of the people who support me—all of these things were getting together and became a gold medal.” Even when describing friends, Westerners tend to use trait-describing adjectives (“*she is helpful*”), whereas East Asians more often use verbs that describe behaviors in context (“*she helps her friends*”) (Heine & Buchtel, 2009; Maass et al., 2006).

Individualism’s benefits can come at the cost of more loneliness, higher divorce and homicide rates, and more stress-related disease (Popenoe, 1993; Triandis et al., 1988). Demands for more romance and personal fulfillment in marriage can subject relationships to more pressure (Dion & Dion, 1993). In one survey, “keeping romance alive” was rated as important to a good marriage by 78 percent of U.S. women but only 29 percent of Japanese women (*American Enterprise*, 1992). In China, love songs often express enduring commitment and friendship (Rothbaum & Tsang, 1998): “We will be together from now on. . . . I will never change from now to forever.”

**Figure 59.3**

A child like no other Americans' individualist tendencies are reflected in their choice of names for their babies. In recent years, the percentage of American babies receiving one of that year's 10 most common names has plunged. (Adapted from Twenge et al., 2010.)

Before You Move On

▶ ASK YOURSELF

Which concept best describes you—collectivist or individualist? Do you fit completely in either category, or are you sometimes a collectivist and sometimes an individualist?

▶ TEST YOURSELF

How do individualist and collectivist cultures differ?

Answers to the Test Yourself questions can be found in Appendix E at the end of the book.

Module 59 Review

59-1

Who first proposed the social-cognitive perspective, and how do social-cognitive theorists view personality development?

- Albert Bandura first proposed the *social-cognitive perspective*, which views personality as the product of the interaction between a person's traits (including thinking) and the situation—the social context.
- The *behavioral approach* contributes an understanding that our personality development is affected by learned responses.
- Social-cognitive researchers apply principles of learning, as well as cognition and social behavior, to personality.
- *Reciprocal determinism* is a term describing the interaction and mutual influence of behavior, internal personal factors, and environmental factors.
- Research on how we interact with our environment evolved into research on the effects of optimism and pessimism, which led to a broader *positive psychology*.

59-2

How do social-cognitive researchers explore behavior, and what criticism have they faced?

- Social-cognitive researchers tend to believe that the best way to predict someone's behavior in a given situation is to observe that person's behavior in similar situations.
- They have been faulted for underemphasizing the importance of unconscious dynamics, emotions, and inner traits. Their response is that the social-cognitive perspective builds on psychology's well-established concepts of learning and cognition and reminds us of the power of situations.

59-3

Why has psychology generated so much research on the self? How important is self-esteem to psychology and to human well-being?

- The *self* is the center of personality, organizing our thoughts, feelings, and actions.
- Considering possible selves helps motivate us toward positive development, but focusing too intensely on ourselves can lead to the *spotlight effect*.
- High *self-esteem* (our feeling of self-worth) is beneficial, but unrealistically high self-esteem is dangerous (linked to aggressive behavior) and fragile.
- *Self-efficacy* is our sense of competence.

59-4

What evidence reveals self-serving bias, and how do defensive and secure self-esteem differ?

- *Self-serving bias* is our tendency to perceive ourselves favorably, as when viewing ourselves as better than average or when accepting credit for our successes but not blame for our failures.
- Defensive self-esteem is fragile, focuses on sustaining itself, and views failure or criticism as a threat.
- Secure self-esteem enables us to feel accepted for who we are.

59-5

How do individualist and collectivist cultures influence people?

- Within any culture, the degree of *individualism* or *collectivism* varies from person to person. Cultures based on self-reliant individualism, like those found in North America and Western Europe, tend to value personal independence and individual achievement. They define identity in terms of self-esteem, personal goals and attributes, and personal rights and liberties. Cultures based on socially connected collectivism, like those in many parts of Asia and Africa, tend to value interdependence, tradition, and harmony, and they define identity in terms of group goals, commitments, and belonging to one's group.

Multiple-Choice Questions

1. Who of the following is considered the leading advocate of personality's social-cognitive approach?
 - a. Gordon Allport
 - b. Carl Jung
 - c. Karen Horney
 - d. Carl Rogers
 - e. Albert Bandura
2. The way we explain negative and positive events is called
 - a. personal control.
 - b. reciprocal determinism.
 - c. positive psychology.
 - d. attributional style.
 - e. situational assessment.
3. Which of the following is an example of an assessment likely to be used by a social-cognitive psychologist?
 - a. A student teacher is formally observed and evaluated in front of the classroom.
 - b. A person applying for a managerial position takes the Myers-Briggs Type Indicator.
 - c. A defendant in a criminal case is interviewed by a court-appointed psychologist.
 - d. In a premarriage counseling session, a young couple responds to ambiguous inkblots.
 - e. A depressed young man is asked by his therapist to relax on a couch and talk about whatever comes to mind.
4. Which of the following is an example of self-efficacy?
 - a. Manuela believes others are always watching her.
 - b. Abraham believes he is a good person.
 - c. Rasheed believes he is a competent skater.
 - d. Saundra believes it rained because she's been wishing for rain for days.
 - e. Igor maintains his optimism despite doing poorly in his math class.
5. Which of the following is most likely to be true of a person from an individualistic culture?
 - a. His behavior would be a reflection of his personality and attitudes.
 - b. He would cope by accommodating to reality.
 - c. He would view his life task as fitting in and maintaining connections.
 - d. He would strive to develop a few close and enduring relationships.
 - e. He would focus on his duty to his family.

Practice FRQs

1. Briefly describe the two main components of the self-serving bias.
2. Heidi is an exceptionally avid reader of books. Explain how the three types of factors in reciprocal determinism might interact to support Heidi's desire to read.

Answer

1 point: People are more likely to take credit for their successes than their failures.

1 point: Most people see themselves as above average.

(3 points)

AP[®] Exam Practice Questions

Multiple-Choice Questions

- A question on the Minnesota Multiphasic Personality Inventory (MMPI) such as “I get angry sometimes” is included to determine what about the test-taker?
 - Whether the person has a personality disorder.
 - If the person needs immediate help for anger management.
 - If the person is more extraverted than introverted.
 - Whether the person has a stronger id or superego.
 - If the person is answering the questions truthfully.
- Albert Bandura proposed the social-cognitive perspective, which
 - explains the nature–nurture debate.
 - predicts human behavior.
 - focuses on how our environment controls us.
 - explains human motivation.
 - emphasizes the interaction of our traits with our situations.

3. According to Sigmund Freud, which of the following defense mechanisms buries threatening or upsetting events in the unconscious?
 - a. Regression
 - b. Displacement
 - c. Repression
 - d. Projection
 - e. Rationalization
4. Athletes who often privately credit their victories to their own abilities, and their losses to bad breaks, lousy officiating, or the other team's exceptional performance, are exhibiting which psychological concept?
 - a. A low self-esteem
 - b. The self-serving bias
 - c. Pessimism
 - d. The spotlight effect
 - e. Incompetence
5. What did Abraham Maslow call the process of fulfilling our potential?
 - a. Love needs
 - b. Self-esteem
 - c. Self-actualization
 - d. Self-transcendence
 - e. Hierarchy of needs
6. Which term is defined as all the thoughts and feelings we have in response to the question, "Who am I?"
 - a. Self-concept
 - b. Ideal self
 - c. Self-esteem
 - d. Empathy
 - e. Self-acceptance
7. What did Sigmund Freud call his theory of personality and the associated treatment techniques?
 - a. Psychoanalysis
 - b. Humanism
 - c. The self-concept
 - d. Psychosexual stages
 - e. Free association
8. Which term describes questionnaires that cover a wide range of feelings and behaviors and are designed to assess several traits?
 - a. Factor analysis studies
 - b. Peer reports
 - c. Achievement tests
 - d. Cognition tests
 - e. Personality inventories
9. Someone from a collectivist culture is more likely to do what?
 - a. Develop a strong sense of self
 - b. Give priority to group goals
 - c. Form casual, often temporary relationships
 - d. Achieve personal goals
 - e. Focus on how they are different from the group
10. Critics of humanistic psychology have suggested that this theory fails to appreciate the reality of our human capacity for which of the following?
 - a. Empathy
 - b. Love
 - c. Negativity
 - d. Evil
 - e. Laziness
11. Amy was sure everyone noticed how nervous she was when she spoke in front of the entire school, but later no one that she talked to mentioned it. What is the term for the belief that others are always noticing and evaluating us more than they really are?
 - a. Self-monitoring
 - b. Self-schemas
 - c. Possible selves
 - d. The spotlight effect
 - e. The social-cognitive perspective
12. In Brad Bushman and Roy Baumeister's research, how did people with unrealistically high self-esteem react when they were criticized?
 - a. They became exceptionally aggressive.
 - b. Many were more receptive to the criticism.
 - c. Some became easily depressed.
 - d. Most worked harder to do better the next time.
 - e. They quit the task without completing it.
13. According to Carl Rogers, when we are in a good marriage, a close family, or an intimate friendship, we are free to be spontaneous without fearing the loss of others' esteem. What did he call this accepting attitude?
 - a. A peak experience
 - b. Unconditional positive regard
 - c. Self-transcendence
 - d. Humanistic psychology
 - e. Our self-concept
14. Children's TV-viewing habits (past behavior) influence their viewing preferences (internal personal factor), which influence how television (environmental factor) affects their current behavior. What is this an example of?
 - a. Personal control
 - b. Learned helplessness
 - c. Reciprocal determinism
 - d. The Big Five traits
 - e. Implicit learning

Free-Response Questions

- One important difference between psychological perspectives on personality involves how each perspective tries to measure personality. Briefly explain how each of the following perspectives views personality measurement, using appropriate psychological terminology.
 - Psychodynamic perspective
 - Humanistic perspective
 - Trait theorists

Rubric for Free-Response Question 1

1 point: The psychodynamic perspective views the goal of personality measurement as revealing the unconscious conflicts and impulses that drive and create our personality. Projective tests (such as the TAT or Rorschach test) are used to allow individuals to “project” their unconscious desires and impulses on to the test so that they are revealed to the therapist and client.  Pages 565–567

1 point: Humanistic theorists are skeptical about attempts to measure personality. They view personality tests and other attempts at measuring and quantifying personality as potentially depersonalizing, reducing the complexity of a person to one of a few generalized categories.  Page 573

1 point: Trait theorists attempt to measure personality through personality inventories, such as the MMPI. They are most interested in knowing where a person fits on each of the Big Five personality factors.  Pages 578–582

Multiple-choice self-tests and more may be found at www.worthpublishers.com/MyersAP2e

- Alejandro has joined an online dating service in an attempt to meet some new people. He met a woman named Sakura through the website and agreed to go out on a date with her because they have many things in common.

Explain how the following concepts could relate to Alejandro and Sakura’s date:

- Self-concept
- Self-efficacy
- Extraversion/introversion
- Spotlight effect

(4 points)

- Maylin has a negative attitude and is disrespectful to her peers. She is unhappy at work and has not been performing at her job as well as in the past. Unfortunately, Maylin blames her co-workers for mistakes that have been made and feels as if the world is against her.

A. Explain how each of the following psychological concepts might explain Maylin’s *negative* or *unpleasant* behavior.

- Self-serving bias
- Displacement

B. Explain how each of the following psychological concepts might *help* Maylin become more positive in her daily life.

- Self-actualization
- Sublimation
- Unconditional positive regard

Unit XI

Testing and Individual Differences

Modules

- 60 Introduction to Intelligence
- 61 Assessing Intelligence
- 62 The Dynamics of Intelligence
- 63 Studying Genetic and Environmental Influences on Intelligence
- 64 Group Differences and the Question of Bias

Three huge controversies have sparked recent debate in and beyond psychology. First is the “memory war,” over whether traumatic experiences are repressed and can later be recovered, with therapeutic benefit. The second great controversy is the “gender war,” over the extent to which nature and nurture shape our behaviors as men and women. In this unit, we meet the “intelligence war”: Does each of us have an inborn general mental capacity (intelligence), and can we quantify this capacity as a meaningful number?

School boards, courts, and scientists debate the use and fairness of tests that assess people’s mental abilities and assign them a score. Is intelligence testing a constructive way to guide people toward suitable opportunities? Or is it a potent, discriminatory weapon camouflaged as science? First, some basic questions:

- What is intelligence?
- How can we best assess it?
- To what extent does it result from heredity and from environmental influence?

- What do test score differences among individuals and groups really mean? Should we use such differences to track the abilities of public school students? To admit them to colleges or universities? To hire them?

This unit offers answers. It identifies a variety of mental gifts. And it concludes that the recipe for high achievement blends talent and grit.

Module 60

Introduction to Intelligence

Module Learning Objectives

- 60-1** Discuss the difficulty of defining *intelligence*.
- 60-2** Present arguments for and against considering intelligence as one general mental ability.
- 60-3** Compare Gardner's and Sternberg's theories of intelligence.
- 60-4** Describe the four components of emotional intelligence.
- 60-5** Describe the relationship between intelligence and brain anatomy.
- 60-6** Describe the relationship between intelligence and neural processing speed.

60-1 How is *intelligence* defined?

Psychologists debate: Should we consider intelligence as one aptitude or many? As linked to cognitive speed? As neurologically measurable? On this much, intelligence experts agree: Intelligence is a concept and not a "thing."

In many research studies, *intelligence* has been operationally defined as whatever intelligence tests measure, which has tended to be school smarts. But intelligence is not a quality like height or weight, which has the same meaning to everyone around the globe. People assign the term *intelligence* to the qualities that enable success in their own time and in their own culture (Sternberg & Kaufman, 1998). In the Amazon rain forest, *intelligence* may be understanding the medicinal qualities of local plants. In a North American high school, it may be mastering difficult concepts in tough courses. In both locations, **intelligence** is the ability to learn from experience, solve problems, and use knowledge to adapt to new situations. An **intelligence test** assesses people's mental abilities and compares them with others, using numerical scores.

intelligence mental quality consisting of the ability to learn from experience, solve problems, and use knowledge to adapt to new situations.

intelligence test a method for assessing an individual's mental aptitudes and comparing them with those of others, using numerical scores.

Hands-on healing The socially constructed concept of intelligence varies from culture to culture. This natural healer in India displays his intelligence in his knowledge about his medicinal plants and understanding of the needs of the people he is helping.

Hemis/Alamy

Is Intelligence One General Ability or Several Specific Abilities?

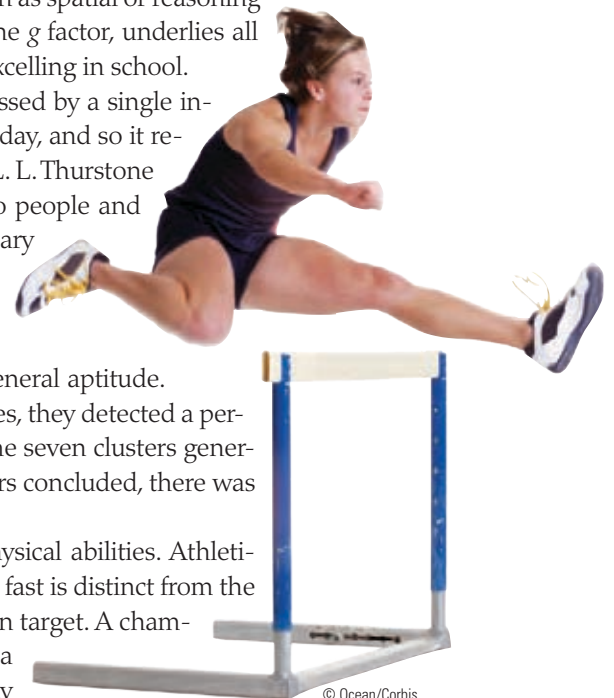

60-2 What are the arguments for and against considering intelligence as one general mental ability?

You probably know some people with talents in science, others who excel in social studies, and still others gifted in athletics, art, music, or dance. You may also know a talented artist who is stumped by the simplest math problem, or a brilliant math student with little aptitude for literary discussion. Are all these people intelligent? Could you rate their intelligence on a single scale? Or would you need several different scales?

Charles Spearman (1863–1945) believed we have one **general intelligence** (often shortened to **g**). He granted that people often have special abilities that stand out and he helped develop **factor analysis**, a statistical procedure that identifies clusters of related items. But Spearman also found that those who score high in one area, such as verbal intelligence, typically score higher than average in other areas, such as spatial or reasoning ability. Spearman believed a common skill set, the **g** factor, underlies all intelligent behavior, from navigating the sea to excelling in school.

This idea of a general mental capacity expressed by a single intelligence score was controversial in Spearman's day, and so it remains. One of Spearman's early opponents was L. L. Thurstone (1887–1955). Thurstone gave 56 different tests to people and mathematically identified seven clusters of primary mental abilities (word fluency, verbal comprehension, spatial ability, perceptual speed, numerical ability, inductive reasoning, and memory). Thurstone did not rank people on a single scale of general aptitude. But when other investigators studied these profiles, they detected a persistent tendency: Those who excelled in one of the seven clusters generally scored well on the others. So, the investigators concluded, there was still some evidence of a **g** factor.

We might, then, liken mental abilities to physical abilities. Athleticism is not one thing but many. The ability to run fast is distinct from the eye-hand coordination required to throw a ball on target. A champion weightlifter rarely has the potential to be a skilled ice skater. Yet there remains some tendency

AP® Exam Tip

David Myers identified three “huge controversies” in the unit opener. All three are covered extensively in this book, and all three will probably show up on the AP® exam.

general intelligence (*g*)

a general intelligence factor that, according to Spearman and others, underlies specific mental abilities and is therefore measured by every task on an intelligence test.

factor analysis

a statistical procedure that identifies clusters of related items (called *factors*) on a test; used to identify different dimensions of performance that underlie a person's total score.

for good things to come packaged together—for running speed and throwing accuracy to correlate, thanks to general athletic ability. So, too, with intelligence. Several distinct abilities tend to cluster together and to correlate enough to define a general intelligence factor.

Satoshi Kanazawa (2004, 2010) argues that general intelligence evolved as a form of intelligence that helps people solve *novel* problems—how to stop a fire from spreading, how to find food during a drought, how to reunite with one’s tribe on the other side of a flooded river. More common problems—such as how to mate or how to read a stranger’s face or how to find your way back to camp—require a different sort of intelligence. Kanazawa asserts that general intelligence scores *do* correlate with the ability to solve various novel problems (like those found in academic and many vocational situations) but *do not* much correlate with individuals’ skills in *evolutionarily familiar* situations—such as marrying and parenting, forming close friendships, and navigating without maps. No wonder academic and social skills may come in different bodies.

Theories of Multiple Intelligences

60-3 How do Gardner’s and Sternberg’s theories of multiple intelligences differ?

Since the mid-1980s, some psychologists have sought to extend the definition of *intelligence* beyond Spearman’s and Thurstone’s academic smarts.

GARDNER’S EIGHT INTELLIGENCES

Howard Gardner (1983, 2006) views intelligence as multiple abilities that come in different packages. Brain damage, for example, may destroy one ability but leave others intact. And consider people with **savant syndrome**, who often score low on intelligence tests but have an island of brilliance (Treffert & Wallace, 2002). Some have virtually no language ability, yet are able to compute numbers as quickly and accurately as an electronic calculator, or identify the day of the week corresponding to any given historical date, or render incredible works of art or musical performance (Miller, 1999). About 4 in 5 people with savant syndrome are males, and many also have autism spectrum disorder (ASD; see Module 47).

The late memory whiz Kim Peek, a savant who did not have ASD, was the inspiration for the movie *Rain Man*. In 8 to 10 seconds, he could read and remember a page. During his lifetime, he memorized 9000 books, including Shakespeare and the Bible. He learned maps from the front of phone books and could provide GPS-like travel directions within any major U.S. city. Yet he could not button his clothes. And he had little capacity for abstract concepts. Asked by his father at a restaurant to “lower your voice,” he slid lower in his chair to lower his voice box. Asked for Lincoln’s Gettysburg Address, he responded, “227 North West Front Street. But he only stayed there one night—he gave the speech the next day” (Treffert & Christensen, 2005).

Using such evidence, Gardner argues that we do not have *an* intelligence, but rather *multiple intelligences* (FIGURE 60.1 on the next page), including the verbal and mathematical aptitudes assessed by standard tests. Thus, the computer programmer, the poet, the street-smart adolescent who becomes a crafty executive, and the basketball team’s point guard exhibit different kinds of intelligence (Gardner, 1998a).

Wouldn’t it be nice if the world were so just that being weak in one area would be compensated by genius in another? Alas, say Gardner’s critics, the world is not just (Ferguson, 2009; Scarr, 1989). Recent research, using factor analysis, has confirmed that there *is* a general intelligence factor (Johnson et al., 2008): *g* matters. It predicts performance on various complex tasks and in various jobs (Gottfredson,

“*g* is one of the most reliable and valid measures in the behavioral domain . . . and it predicts important social outcomes such as educational and occupational levels far better than any other trait.” -BEHAVIOR GENETICIST ROBERT PLOMIN (1999)

savant syndrome a condition in which a person otherwise limited in mental ability has an exceptional specific skill, such as in computation or drawing.

Islands of genius: Savant syndrome Matt Savage, an award-winning jazz musician, is a Berklee College of Music graduate who has released many albums. His success has been hard-won given his early childhood diagnosis of what is now called autism spectrum disorder, which came with struggles to communicate and an initial inability to tolerate sounds of any kind.

Joanne Prather/The Boston Globe via Getty Images

Figure 60.1
Gardner's eight intelligences

grit in psychology, grit is passion and perseverance in the pursuit of long-term goals.

Try This

For more on how self-disciplined grit feeds achievement, see Module 82.

2002a,b, 2003a,b; see also **FIGURE 60.2**). Much as jumping ability is not a predictor of jumping performance when the bar is set a foot off the ground—but becomes a predictor when the bar is set higher—so extremely high cognitive ability scores predict exceptional attainments, such as doctoral degrees and publications (Kuncel & Hezlett, 2010).

Even so, “success” is not a one-ingredient recipe. High intelligence may help you get into a good college and ultimately a desired profession, but it won’t make you successful once there. The recipe for success combines talent with **grit**: Those who become highly successful tend also to be conscientious, well-connected, and doggedly energetic.

Figure 60.2

Smart and rich? Jay Zagorsky (2007) tracked 7403 participants in the U.S. National Longitudinal Survey of Youth across 25 years. As shown in this scatterplot, their intelligence scores shared a small but significant correlation (+.30) with their later income. Each dot indicates a given youth’s intelligence score and later adult income.

K. Anders Ericsson (2002, 2007; Ericsson et al., 2007) reports a *10-year rule*: A common ingredient of expert performance in chess, dancing, sports, computer programming, music, and medicine is “about 10 years of intense, daily practice.” Various animal species, including bees, birds, and chimps, likewise require time and experience to acquire peak expertise in skills such as foraging (Helton, 2008). As with humans, animal performance therefore tends to peak near midlife.

Courtesy of Cameras on Wheels

Spatial intelligence genius In 1998, World Checkers Champion Ron “Suki” King of Barbados set a new record by simultaneously playing 385 players in 3 hours and 44 minutes. Thus, while his opponents often had hours to plot their game moves, King could only devote about 35 seconds to each game. Yet he still managed to win all 385 games!

STERNBERG’S THREE INTELLIGENCES

Robert Sternberg (1985, 1999, 2003) agrees that there is more to success than traditional intelligence and also agrees with Gardner’s idea of multiple intelligences. But he proposes a *triarchic theory* of three, not eight, intelligences:

- **Analytical (academic problem-solving) intelligence** is assessed by traditional intelligence tests, which present well-defined problems having a single right answer. Such tests predict school grades reasonably well and vocational success more modestly.
- **Creative intelligence** is demonstrated in reacting adaptively to novel situations and generating novel ideas. Many inventions result from such creative problem solving.
- **Practical intelligence** is required for everyday tasks, which may be ill-defined, with multiple solutions. Managerial success, for example, depends less on academic problem-solving skills than on a shrewd ability to manage oneself, one’s tasks, and other people. Sternberg and Richard Wagner (1993, 1995) offer a test of practical managerial intelligence that measures skill at writing effective memos, motivating people, delegating tasks and responsibilities, reading people, and promoting one’s own career. Business executives who score relatively high on this test tend to earn high salaries and receive high performance ratings.

With support from the U.S. College Board® (which administers the Advanced Placement® Program as well as the widely used SAT Reasoning Test™ to U.S. college and university applicants), Sternberg (2006, 2007, 2010) and a team of collaborators have developed new measures of creativity (such as thinking up a caption for an untitled cartoon) and practical thinking (such as figuring out how to move a large bed up a winding staircase). Their initial data indicate that these more comprehensive assessments improve prediction of American students’ first-year college grades, and they do so with reduced ethnic-group differences.

Although Gardner and Sternberg differ on specific points, they agree that multiple abilities can contribute to life success. They also agree that the differing varieties of giftedness add spice to life and challenges for education. Under their influence, many teachers have been trained to appreciate such variety and to apply multiple intelligence theory in their classrooms.

“You have to be careful, if you’re good at something, to make sure you don’t think you’re good at other things that you aren’t necessarily so good at. . . . Because I’ve been very successful at [software development] people come in and expect that I have wisdom about topics that I don’t.”
-BILL GATES (1998)

“You’re wise, but you lack tree smarts.”

David R. Frazier Photolibrary, Inc./Alamy

Street smarts This child selling candy on the streets of Manaus, Brazil, is developing practical intelligence at a very young age.

Emotional Intelligence

60-4 What are the four components of emotional intelligence?

emotional intelligence the ability to perceive, understand, manage, and use emotions.

Also distinct from academic intelligence is *social intelligence*—the know-how involved in successfully comprehending social situations. People with high social intelligence can read social situations the way a skilled football player reads the defense or a seafarer reads the weather. The concept was first proposed in 1920 by psychologist Edward Thorndike, who noted, “The best mechanic in a factory may fail as a foreman for lack of social intelligence” (Goleman, 2006, p. 83). Later psychologists have marveled that high-aptitude people are “not, by a wide margin, more effective . . . in achieving better marriages, in successfully raising their children, and in achieving better mental and physical well-being” (Epstein & Meier, 1989). Others have explored the difficulty that some smart people have processing and managing social information (Cantor & Kihlstrom, 1987; Weis & Süß, 2007). This idea is especially significant for an aspect of social intelligence that John Mayer, Peter Salovey, and David Caruso (2002, 2008) have called **emotional intelligence**. They have developed a test that assesses four emotional intelligence components:

- *Perceiving* emotions (to recognize them in faces, music, and stories)
- *Understanding* emotions (to predict them and how they change and blend)
- *Managing* emotions (to know how to express them in varied situations)
- *Using* emotions to enable adaptive or creative thinking

Mayer, Salovey, and Caruso caution against stretching “emotional intelligence” to include varied traits such as self-esteem and optimism. Rather, emotionally intelligent people are both socially and self-aware. And in both the United States and Germany, those scoring high on managing emotions enjoy higher-quality interactions with friends (Lopes et al., 2004). They avoid being hijacked by overwhelming depression, anxiety, or anger. Being sensitive to emotional cues, they know what to say to soothe a grieving friend, encourage a colleague, and manage a conflict.

Emotional intelligence is less a matter of conscious effort than of one’s unconscious processing of emotional information (Fiori, 2009). Yet the outgrowths of this automatic processing become visible. Across dozens of studies in many countries, those scoring high in emotional intelligence exhibit somewhat better job performance (Joseph & Newman, 2010; Van Rooy & Viswesvaran, 2004; Zeidner et al., 2008). They also can delay gratification in pursuit of long-range rewards, rather than being overtaken by immediate impulses. They are emotionally in tune with others, and thus often succeed in career, marriage, and parenting situations where academically smarter (but emotionally less intelligent) people fail (Cherniss, 2010a,b; Ciarrochi et al., 2006).

Brain damage reports have provided extreme examples of the results of diminished emotional intelligence in people with high general intelligence. Neuroscientist Antonio Damasio (1994) tells of Elliot, who had a brain tumor removed: “I never saw a tinge of emotion in my many hours of conversation with him, no sadness, no impatience, no frustration.” Shown disturbing pictures of injured people, destroyed communities, and natural disasters, Elliot showed—and realized he felt—no emotion. He knew but he could not feel. Unable to intuitively adjust his behavior in response to others’ feelings, Elliot lost his job. He went bankrupt. His marriage collapsed. He remarried and divorced again. At last report, he was dependent on a disability check and custodial care from a sibling.

Some scholars, however, are concerned that emotional intelligence stretches the concept of intelligence too far. Multiple-intelligence man Howard Gardner (1999b) welcomes our stretching the concept into such realms as music and information about ourselves and others. But let us also, he says, respect emotional sensitivity, creativity, and motivation as important but different. Stretch “intelligence” to include everything we prize and it will lose its meaning.

“I worry about [intelligence] definitions that collapse assessments of our cognitive powers with statements about the kind of human beings we favor.”
—HOWARD GARDNER, “RETHINKING THE CONCEPT OF INTELLIGENCE,” 2000

Is Intelligence Neurologically Measurable?

You know it: You are smarter than some people and not as smart as others. Question: What in that heart of smarts—your brain—creates this difference? Is it your brain's relative *size*? The amount of certain brain *tissue*? Your brain networks' *efficiency*?

Brain Size and Complexity

60-5 To what extent is intelligence related to brain anatomy?

After the brilliant English poet Lord Byron died in 1824, doctors discovered that his brain was a massive 5 pounds, not the normal 3 pounds. Three years later, Beethoven died and his brain was found to have exceptionally numerous and deep convolutions. Such observations set brain scientists off studying the brains of other geniuses (Burrell, 2005). Do people with big brains have big smarts?

Alas, some geniuses had small brains, and some dim-witted criminals had brains like Byron's. More recent studies that directly measure brain volume using MRI scans do reveal correlations of about +.33 between brain size (adjusted for body size) and intelligence score (Carey, 2007; McDaniel, 2005). Bigger is better.

One review of 37 brain-imaging studies revealed associations between intelligence and brain size and activity in specific areas, especially within the frontal and parietal lobes (Jung & Haier, 2007; Tang et al., 2010). Intelligence is having ample gray matter (mostly neural cell bodies) plus ample white matter (axons) that make for efficient communication between brain centers (Deary et al., 2009; Haier et al., 2009).

Sandra Witelson would not have been surprised. With the brains of 91 Canadians as a comparison base, Witelson and her colleagues (1999) seized an opportunity to study Einstein's brain. Although not notably heavier or larger in total size than the typical Canadian's brain, Einstein's brain was 15 percent larger in the parietal lobe's lower region—which just happens to be a center for processing mathematical and spatial information.

Brain Function

60-6 To what extent is intelligence related to neural processing speed?

The correlations between brain anatomy and intelligence only begin to explain intelligence differences. Searching for other explanations, neuroscientists are studying the brain's functioning.

As people contemplate a variety of questions like those found on intelligence tests, a frontal lobe area just above the outer edge of the eyebrows becomes especially active—in the left brain for verbal questions, and on both sides for spatial questions (Duncan et al., 2000). Information from various brain areas seems to converge here, suggesting to researcher John Duncan (2000) that it may be a “global workspace for organizing and coordinating information” and that some people may be “blessed with a workspace that functions very, very well.”

Functioning well means functioning efficiently. Brain scans reveal that smart people use less energy to solve problems (Haier, 2009). They are like skilled athletes, for whom agile moves can seem effortless. Agile minds come with agile brains.

So, are more intelligent people literally more quick-witted, much as today's speedier computer chips enable ever more powerful computing? On some tasks they seem to be. Verbal intelligence scores are predictable from the speed with which people retrieve information from memory (Hunt, 1983). Those who recognize quickly that *sink* and *wink* are different words, or that *A* and *a* share the same name, tend to score high in verbal ability. Extremely precocious 12- to 14-year-old college students are especially quick in responding to such tasks (Jensen, 1989). To try to define *quick-wittedness*, researchers are taking a close look at speed of perception and speed of neural processing.

AP® Exam Tip

Do not continue on if you can't remember what terms like *MRI*, *parietal lobe*, and *axon* mean. Now is the time to head back to Unit III for a review. If you do this sort of review frequently, you'll have much better command of the material on the day of the AP® exam.

Figure 60.3**An inspection time task**

A stimulus is flashed before being overridden by a masking image. How long would you need to glimpse the stimulus at the left to answer the question? People who can perceive the stimulus very quickly tend to score somewhat higher on intelligence tests. (Adapted from Deary & Stough, 1996.)

Across many studies, the correlation between intelligence score and the speed of taking in perceptual information tends to be about +.3 to +.5 (Deary & Der, 2005; Sheppard & Vernon, 2008). A typical experiment flashes an incomplete stimulus, as in **FIGURE 60.3**, then a *masking image*—another image that overrides the lingering afterimage of the incomplete stimulus. The researcher then asks participants whether the long side appeared on the right or left. Those whose brains require the least inspection time to register a simple stimulus tend to score somewhat higher on intelligence tests (Caryl, 1994; Deary & Caryl, 1993; Reed & Jensen, 1992).

Perhaps people who process more quickly accumulate more information. Or perhaps, as one Australian-Dutch research team has found, processing speed and intelligence correlate not because one causes the other but because they share an underlying genetic influence (Luciano et al., 2005).

* * *

For a summary of Spearman's, Thurstone's, Gardner's, and Sternberg's theories, see **TABLE 60.1**.

Table 60.1 Comparing Theories of Intelligence

Theory	Summary	Strengths	Other Considerations
<i>Spearman's general intelligence (g)</i>	A basic intelligence predicts our abilities in varied academic areas.	Different abilities, such as verbal and spatial, do have some tendency to correlate.	Human abilities are too diverse to be encapsulated by a single general intelligence factor.
<i>Thurstone's primary mental abilities</i>	Our intelligence may be broken down into seven factors: word fluency, verbal comprehension, spatial ability, perceptual speed, numerical ability, inductive reasoning, and memory.	A single <i>g</i> score is not as informative as scores for seven primary mental abilities.	Even Thurstone's seven mental abilities show a tendency to cluster, suggesting an underlying <i>g</i> factor.
<i>Gardner's multiple intelligences</i>	Our abilities are best classified into eight independent intelligences, which include a broad range of skills beyond traditional school smarts.	Intelligence is more than just verbal and mathematical skills. Other abilities are equally important to our human adaptability.	Should all of our abilities be considered <i>intelligences</i> ? Shouldn't some be called talents?
<i>Sternberg's triarchic theory</i>	Our intelligence is best classified into three areas that predict real-world success: analytical, creative, and practical.	These three facets can be reliably measured.	<ol style="list-style-type: none"> 1. These three facets may be less independent than Sternberg thought and may actually share an underlying <i>g</i> factor. 2. Additional testing is needed to determine whether these facets can reliably predict success.

Before You Move On

▶ ASK YOURSELF

The modern concept of multiple intelligences (as proposed by Gardner and Sternberg) assumes that the analytical school smarts measured by traditional intelligence tests are important abilities but that other abilities are also important. Different people have different gifts. What are yours?

▶ TEST YOURSELF

Joseph, a Harvard Law School student, has a straight-A average, writes for the *Harvard Law Review*, and will clerk for a Supreme Court justice next year. His grandmother, Judith, is very proud of him, saying he is way more intelligent than she ever was. But Joseph is also very proud of Judith: As a young woman, she was imprisoned by the Nazis. When the war ended, she walked out of Germany, contacted an agency helping refugees, and began a new life in the United States as an assistant chef in her cousin's restaurant. According to the definition of intelligence in this unit, is Joseph the only intelligent person in this story? Why or why not?

Answers to the Test Yourself questions can be found in Appendix E at the end of the book.

Module 60 Review

60-1 How is *intelligence* defined?

- *Intelligence* is a mental quality consisting of the ability to learn from experience, solve problems, and use knowledge to adapt to new situations.
- An *intelligence test* aims to assess these qualities and compare them with those of others, using a numerical score.

60-2 What are the arguments for and against considering intelligence as one general mental ability?

- Charles Spearman proposed that we have one *general intelligence* (*g*). He helped develop *factor analysis*, a statistical procedure that identifies clusters of related mental abilities.
- L. L. Thurstone disagreed and identified seven different clusters of mental abilities. Yet a tendency remained for high scorers in one cluster to score high in other clusters.
- Studies indicate that *g* scores are most predictive in novel situations and do not much correlate with skills in evolutionarily familiar situations.

60-3 How do Gardner's and Sternberg's theories of multiple intelligences differ?

- *Savant syndrome* seems to support Howard Gardner's view that we have multiple intelligences. He proposed eight independent intelligences: linguistic, logical-mathematical, musical, spatial, bodily-kinesthetic, intrapersonal, interpersonal, and naturalist.
- Robert Sternberg's triarchic theory proposes three intelligence areas that predict real-world skills: analytical (academic problem solving), creative, and practical.

60-4 What are the four components of emotional intelligence?

- *Emotional intelligence*, which is an aspect of social intelligence, is the ability to perceive, understand, manage, and use emotions.
- Emotionally intelligent people achieve greater personal and professional success.
- Some critics question whether calling these abilities "intelligence" stretches that concept too far.

60-5 To what extent is intelligence related to brain anatomy?

- Some studies have found a positive correlation between intelligence score and brain size and activity, especially in the frontal and parietal lobes.
- Ample gray matter and white matter enable efficient communication between brain circuits.

60-6 To what extent is intelligence related to neural processing speed?

- People who score high on intelligence tests tend also to have agile brains and score high in speed of perception and speed of neural processing.
- The direction of correlation has not been determined, and some third factor may influence both intelligence and processing speed.

Multiple-Choice Questions

1. According to Robert Sternberg, what kind of intelligence is assessed by traditional intelligence tests?
 - a. Linguistic
 - b. Practical
 - c. Creative
 - d. Spatial
 - e. Analytical
2. According to Charles Spearman and others, which of the following underlies specific mental abilities and is measured by every task on an intelligence test?
 - a. Savant syndrome
 - b. General intelligence (*g*)
 - c. Factor analysis
 - d. Intelligence
 - e. Emotional intelligence
3. Of the following, which term best describes the condition in which a person with limited mental ability excels at a specific skill such as computation?
 - a. Savant syndrome
 - b. *g* factor
 - c. Creative intelligence
 - d. Emotional intelligence
 - e. Street smarts
4. Which of the following is not a component of emotional intelligence?
 - a. Understanding emotions
 - b. Perceiving emotions
 - c. Using emotions
 - d. Managing emotions
 - e. Inventing emotions

Practice FRQs

1. Give a summary, a strength, and a weakness of Charles Spearman's idea of general intelligence.
2. Name and describe Robert Sternberg's three intelligences.

(3 points)

Answer

1 point: General intelligence is basic intelligence that predicts our abilities in varied academic areas.

1 point: A strength of this idea is that different abilities, such as verbal and spatial, tend to correlate.

1 point: A weakness of this idea is that human abilities are too diverse to be explained by a single general intelligence factor.

Module 61

Assessing Intelligence

Module Learning Objectives

- 61-1** Discuss the history of intelligence testing.
- 61-2** Distinguish between aptitude and achievement tests.
- 61-3** Explain the meaning of standardization, and describe the normal curve.
- 61-4** Explain the meanings of reliability and validity.

How do we assess intelligence? And what makes a test credible? Answering these questions begins with a look at why psychologists created tests of mental abilities and how they have used those tests.

The Origins of Intelligence Testing

- 61-1** When and why were intelligence tests created?

Some societies concern themselves with promoting the collective welfare of the family, community, and society. Other societies emphasize individual opportunity. Plato, a pioneer of the individualist tradition, wrote more than 2000 years ago in *The Republic* that “no two persons are born exactly alike; but each differs from the other in natural endowments, one being suited for one occupation and the other for another.” As heirs to Plato’s individualism, people in Western societies have pondered how and why individuals differ in mental ability.

Western attempts to assess such differences began in earnest over a century ago. The English scientist Francis Galton (1822–1911) had a fascination with measuring human traits. When his cousin Charles Darwin proposed that nature selects successful traits through the survival of the fittest, Galton wondered if it might be possible to measure “natural ability” and to encourage those of high ability to mate with one another. At the 1884 London Exposition, more than 10,000 visitors received his assessment of their “intellectual strengths” based on such things as reaction time, sensory acuity, muscular power, and body proportions. But alas, on these measures, well-regarded adults and students did not outscore others. Nor did the measures correlate with one another.

Although Galton’s quest for a simple intelligence measure failed, he gave us some statistical techniques that we still use (as well as the phrase “nature and nurture”). And his persistent belief in the inheritance of genius—reflected in his book, *Hereditary Genius*—illustrates an important lesson from both the history of intelligence research and the history of science: Although science itself strives for objectivity, individual scientists are affected by their own assumptions and attitudes.

Alfred Binet “Some recent philosophers have given their moral approval to the deplorable verdict that an individual’s intelligence is a fixed quantity, one which cannot be augmented. We must protest and act against this brutal pessimism” (Binet, 1909, p. 141).

“The IQ test was invented to predict academic performance, nothing else. If we wanted something that would predict life success, we’d have to invent another test completely.” -SOCIAL PSYCHOLOGIST
ROBERT ZAJONC (1984b)

mental age a measure of intelligence test performance devised by Binet; the chronological age that most typically corresponds to a given level of performance. Thus, a child who does as well as the average 8-year-old is said to have a mental age of 8.

Stanford-Binet the widely used American revision (by Terman at Stanford University) of Binet’s original intelligence test.

intelligence quotient (IQ) defined originally as the ratio of mental age (*ma*) to chronological age (*ca*) multiplied by 100 (thus, $IQ = ma/ca \times 100$). On contemporary intelligence tests, the average performance for a given age is assigned a score of 100, with scores assigned to relative performance above or below average.

Alfred Binet: Predicting School Achievement

The modern intelligence-testing movement began at the turn of the twentieth century, when France passed a law requiring that all children attend school. Some children, including many newcomers to Paris, seemed incapable of benefiting from the regular school curriculum and in need of special classes. But how could the schools objectively identify children with special needs?

The French government hesitated to trust teachers’ subjective judgments of children’s learning potential. Academic slowness might merely reflect inadequate prior education. Also, teachers might prejudice children on the basis of their social backgrounds. To minimize bias, France’s minister of public education in 1904 commissioned Alfred Binet (1857–1911) and others to study the problem.

Binet and his collaborator, Théodore Simon, began by assuming that all children follow the same course of intellectual development but that some develop more rapidly. On tests, therefore, a “dull” child should perform as does a typical younger child, and a “bright” child as does a typical older child. Thus, their goal became measuring each child’s **mental age**, the level of performance typically associated with a certain chronological age. The average 9-year-old, then, has a mental age of 9. Children with below-average mental ages, such as 9-year-olds who perform at the level of typical 7-year-olds, would struggle with age-appropriate schoolwork.

To measure mental age, Binet and Simon theorized that mental aptitude, like athletic aptitude, is a general capacity that shows up in various ways. After testing a variety of reasoning and problem-solving questions on Binet’s two daughters, and then on “bright” and “backward” Parisian schoolchildren, Binet and Simon identified items that would predict how well French children would handle their schoolwork.

Note that Binet and Simon made no assumptions concerning *why* a particular child was slow, average, or precocious. Binet personally leaned toward an environmental explanation. To raise the capacities of low-scoring children, he recommended “mental orthopedics” that would help develop their attention span and self-discipline. He believed his intelligence test did not measure inborn intelligence as a meter stick measures height. Rather, it had a single practical purpose: to identify French schoolchildren needing special attention. Binet hoped his test would be used to improve children’s education, but he also feared it would be used to label children and limit their opportunities (Gould, 1981).

Lewis Terman: The Innate IQ

Binet’s fears were realized soon after his death in 1911, when others adapted his tests for use as a numerical measure of inherited intelligence. This began when Stanford University professor Lewis Terman (1877–1956) found that the Paris-developed questions and age norms worked poorly with California schoolchildren. Adapting some of Binet’s original items, adding others, and establishing new age norms, Terman extended the upper end of the test’s range from teenagers to “superior adults.” He also gave his revision the name it retains today—the **Stanford-Binet**. For Terman, intelligence tests revealed the intelligence with which a person was born.

From such tests, German psychologist William Stern derived the famous **intelligence quotient**, or **IQ**. The IQ is simply a person’s mental age divided by chronological age and multiplied by 100 to get rid of the decimal point:

$$IQ = \frac{\text{mental age}}{\text{chronological age}} \times 100$$

Thus, an average child, whose mental and chronological ages are the same, has an IQ of 100. But an 8-year-old who answers questions as would a typical 10-year-old has an IQ of 125.

The original IQ formula worked fairly well for children but not for adults. (Should a 40-year-old who does as well on the test as an average 20-year-old be assigned an IQ of only 50?) Most current intelligence tests, including the Stanford-Binet, no longer compute an IQ in this manner (though the term *IQ* still lingers as a shorthand expression for “intelligence test score”). Instead, they represent the test-taker’s performance *relative to the average performance of others the same age*. This average performance is arbitrarily assigned a score of 100, and about two-thirds of all test-takers fall between 85 and 115.

Terman promoted the widespread use of intelligence testing. His motive was to “take account of the inequalities of children in original endowment” by assessing their “vocational fitness.” In sympathy with Francis Galton’s *eugenics*—a much-criticized nineteenth-century movement that proposed measuring human traits and using the results to encourage only smart and fit people to reproduce—Terman (1916, pp. 91–92) envisioned that the use of intelligence tests would “ultimately result in curtailing the reproduction of feeble-mindedness and in the elimination of an enormous amount of crime, pauperism, and industrial inefficiency” (p. 7).

With Terman’s help, the U.S. government developed new tests to evaluate both newly arriving immigrants and World War I army recruits—the world’s first mass administration of an intelligence test. To some psychologists, the results indicated the inferiority of people not sharing their Anglo-Saxon heritage. Such findings were part of the cultural climate that led to a 1924 immigration law that reduced Southern and Eastern European immigration quotas to less than one-fifth of those for Northern and Western Europe.

Binet probably would have been horrified that his test had been adapted and used to draw such conclusions. Indeed, such sweeping judgments became an embarrassment to most of those who championed testing. Even Terman came to appreciate that test scores reflected not only people’s innate mental abilities but also their education, native language, and familiarity with the culture assumed by the test. Abuses of the early intelligence tests serve to remind us that science can be value-laden. Behind a screen of scientific objectivity, ideology sometimes lurks.

Mrs. Randolph takes mother’s pride too far.

Modern Tests of Mental Abilities

61-2 What’s the difference between achievement and aptitude tests?

By this point in your life, you’ve faced dozens of ability tests: school tests of basic reading and math skills, course exams, intelligence tests, and driver’s license exams, to name just a few. Psychologists classify such tests as either **achievement tests**, intended to *measure* what you have learned, or **aptitude tests**, intended to *predict* your ability to learn a new skill. Exams covering what you have learned in this course (like the AP® Exam) are achievement tests. A college entrance exam, which seeks to predict your ability to do college work, is an aptitude test—a “thinly disguised intelligence test,” says Howard Gardner (1999a). Indeed, total scores on the U.S. SAT® correlated +.82 with general intelligence scores in a national sample of 14- to 21-year-olds (Frey & Detterman, 2004; **FIGURE 61.1** on the next page).

AP® Exam Tip

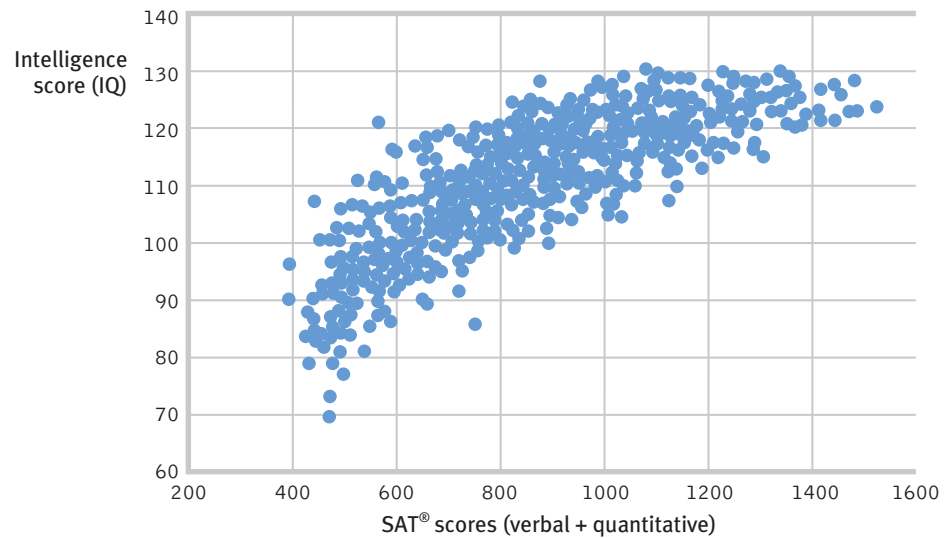

David Myers did not use the terms *nature* or *nurture* as he described the contributions of Binet and Terman, but he dropped many hints that should allow you to figure out who leaned toward the nature position and who leaned toward the nurture position. Can you do it?

achievement test a test designed to assess what a person has learned.

aptitude test a test designed to predict a person’s future performance; aptitude is the capacity to learn.

Figure 61.1

Close cousins: Aptitude and intelligence scores A scatterplot shows the close correlation between intelligence scores and verbal and quantitative SAT® scores. (From Frey and Detterman, 2004.)

Wechsler Adult Intelligence Scale (WAIS) the WAIS is the most widely used intelligence test; contains verbal and performance (nonverbal) subtests.

Richard T. Novitz/Corbis

Matching patterns Block design puzzles test visual abstract processing ability. Wechsler's individually administered intelligence test comes in forms suited for adults and children.

Psychologist David Wechsler created what is now the most widely used individual intelligence test, the **Wechsler Adult Intelligence Scale (WAIS)**, with a version for school-age children (the *Wechsler Intelligence Scale for Children [WISC]*), and another for preschool children. The latest (2008) edition of the WAIS consists of 15 subtests, including these:

- *Similarities*—Reasoning the commonality of two objects or concepts, such as “In what way are wool and cotton alike?”
- *Vocabulary*—Naming pictured objects, or defining words (“What is a guitar?”)
- *Block design*—Visual abstract processing, such as “Using the four blocks, make one just like this.”
- *Letter-number sequencing*—On hearing a series of numbers and letters, repeat the numbers in ascending order, and then the letters in alphabetical order: “R-2-C-1-M-3.”

It yields not only an overall intelligence score, as does the Stanford-Binet, but also separate scores for verbal comprehension, perceptual organization, working memory, and processing speed. Striking differences among these scores can provide clues to cognitive strengths or weaknesses that teachers or therapists can build upon. For example, a low verbal comprehension score combined with high scores on other subtests could indicate a reading or language disability. Other comparisons can help a psychologist or psychiatrist establish a rehabilitation plan for a stroke patient. Such uses are possible, of course, only when we can trust the test results.

Principles of Test Construction

61-3 What are standardization and the normal curve?

To be widely accepted, psychological tests must meet three criteria: They must be *standardized*, *reliable*, and *valid*. The Stanford-Binet and Wechsler tests meet these requirements.

Standardization

The number of questions you answer correctly on an intelligence test would tell us almost nothing. To evaluate your performance, we need a basis for comparing it with others' performance. To enable meaningful comparisons, test-makers first give the test to a representative sample of people. When you later take the test following the same procedures, your score

**Figure 61.2**

The normal curve Scores on aptitude tests tend to form a normal, or bell-shaped, curve around an average score. For the Wechsler scale, for example, the average score is 100.

can be compared with the sample's scores to determine your position relative to others. This process of defining meaningful scores relative to a pretested group is called **standardization**.

Group members' scores typically are distributed in a bell-shaped pattern that forms the **normal curve** shown in **FIGURE 61.2**. No matter what we measure—height, weight, or mental aptitude—people's scores tend to form this roughly symmetrical shape. On an intelligence test, we call the midpoint, the average score, 100. Moving out from the average toward either extreme, we find fewer and fewer people. For both the Stanford-Binet and Wechsler tests, a person's score indicates whether that person's performance fell above or below the average. As Figure 61.2 shows, a performance higher than all but 2 percent of all scores earns an intelligence score of 130. A performance lower than 98 percent of all scores earns an intelligence score of 70.

To keep the average score near 100, the Stanford-Binet and Wechsler scales are periodically restandardized. If you took the WAIS Fourth Edition recently, your performance was compared with a standardization sample who took the test during 2007, not to David Wechsler's initial 1930s sample. If you compared the performance of the most recent standardization sample with that of the 1930s sample, do you suppose you would find rising or declining test performance? Amazingly—given that college entrance aptitude scores were dropping during the 1960s and 1970s—intelligence test performance was improving. This worldwide phenomenon is called the *Flynn effect*, in honor of New Zealand researcher James Flynn (1987, 2009b, 2010), who first calculated its magnitude. As **FIGURE 61.3** indicates, the average person's intelligence test score in 1920 was—by today's standard—only a 76! Such rising performance has been observed in 29 countries, from Canada to rural Australia (Ceci & Kanaya, 2010). Although the gains have recently reversed in Scandinavia, the historic increase is now widely accepted as an important phenomenon (Lynn, 2009; Teasdale & Owen, 2005, 2008).

standardization defining uniform testing procedures and meaningful scores by comparison with the performance of a pretested group.

normal curve the symmetrical, bell-shaped curve that describes the distribution of many physical and psychological attributes. Most scores fall near the average, and fewer and fewer scores lie near the extremes.

AP® Exam Tip

Can you remember why the intelligence test scores in Figure 61.2 are marked off in 15-point intervals? Do the 68 percent and 95 percent areas seem familiar? They should—you've seen this graph before. It's Figure 7.3 from the module on statistical reasoning. Intelligence tests are being used to illustrate that 68 percent of a population will be within one standard deviation of the mean for normally distributed data. Ninety-five percent will be within two standard deviations.

Lewis J. Merrim/Science Source

Figure 61.3

Getting smarter? In every country studied, intelligence test performance rose during the twentieth century, as shown here with U.S. Wechsler and Stanford-Binet test performance between 1918 and 1989. In Britain, test scores have risen 27 points since 1942. (From Hogan, 1995.) Very recent data indicate this trend may have leveled off or may even be reversing.

reliability the extent to which a test yields consistent results, as assessed by the consistency of scores on two halves of the test, on alternate forms of the test, or on retesting.

validity the extent to which a test measures or predicts what it is supposed to. (See also *content validity* and *predictive validity*.)

content validity the extent to which a test samples the behavior that is of interest.

predictive validity the success with which a test predicts the behavior it is designed to predict; it is assessed by computing the correlation between test scores and the criterion behavior. (Also called *criterion-related validity*.)

AP® Exam Tip

Be careful! The terms *reliability* and *validity* have more precise meanings to psychologists than they do to the general public.

The Flynn effect's cause has been a mystery. Did it result from greater test sophistication? (But the gains began before testing was widespread and have even been observed among preschoolers.) Better nutrition? As the nutrition explanation would predict, people have gotten not only smarter but taller. But in post-war Britain, notes Flynn (2009a), the lower-class children gained the most from improved nutrition but the intelligence performance gains were greater among upper-class children. Or did the Flynn effect stem from more education? More stimulating environments? Less childhood disease? Smaller families and more parental investment (Sundet et al., 2008)?

Regardless of what combination of factors explains the rise in intelligence test scores, the phenomenon counters one concern of some hereditarians—that the higher twentieth-century birthrates among those with lower scores would shove human intelligence scores downward (Lynn & Harvey, 2008). Seeking to explain the rising scores, and mindful of global mixing, one scholar has even speculated about the influence of a genetic phenomenon comparable with “hybrid vigor,” which occurs in agriculture when cross-breeding produces corn or livestock superior to the parent plants or animals (Mingroni, 2004, 2007).

Reliability

61-4 What are reliability and validity?

Knowing where you stand in comparison to a standardization group still won't tell us much about your intelligence unless the test has **reliability**—unless it yields dependably consistent scores. To check a test's reliability, researchers retest people. They may use the same test or they may split the test in half to see whether odd-question scores and even-question scores agree. If the two scores generally agree, or *correlate*, the test is reliable. The higher the correlation between the *test-retest* or the *split-half* scores, the higher the test's reliability. The tests we have considered so far—the Stanford-Binet, the WAIS, and the WISC—all have reliabilities of about +.9, which is very high. When retested, people's scores generally match their first score closely.

Validity

High reliability does not ensure a test's **validity**—the extent to which the test actually measures or predicts what it promises. If you use an inaccurate tape measure to measure people's heights, your height report would have high reliability (consistency) but low validity. It is enough for some tests that they have **content validity**, meaning the test taps the pertinent behavior, or *criterion*. The road test for a driver's license has content validity because it samples the tasks a driver routinely faces. Course exams have content validity if they assess one's mastery of a representative sample of course material. But we expect intelligence tests to have **predictive validity**: They should predict the criterion of future performance, and to some extent they do.

Are general aptitude tests as predictive as they are reliable? As critics are fond of noting, the answer is plainly *No*. The predictive power of aptitude tests is fairly strong in the early school years, but later it weakens. Academic aptitude test scores are reasonably good predictors of achievement for children ages 6 to 12, where the correlation between intelligence score and school performance is about +.6 (Jensen, 1980). Intelligence scores correlate even more closely with scores on *achievement tests*: +.81 in one comparison of 70,000 English children's intelligence scores at age 11 with their academic achievement in national exams at age 16 (Deary et al., 2007, 2009). The SAT® exam, used in the United States as a college entrance exam, is less successful in predicting first-year college grades. (The correlation, which is less than +.5, is, however, a bit higher when adjusting for high scorers electing tougher courses [Berry & Sackett, 2009; Willingham et al., 1990].) By the time we get to the Graduate Record Examination® (GRE®, an aptitude test similar to the SAT® exam but for those applying to graduate school), the correlation with graduate school performance is an even more modest but still significant +.4 (Kuncel & Hezlett, 2007).

**Figure 61.4**

Diminishing predictive power Let's imagine a correlation between football linemen's body weight and their success on the field. Note how insignificant the relationship becomes when we narrow the range of weight to 280 to 320 pounds. As the range of data under consideration narrows, its predictive power diminishes.

Why does the predictive power of aptitude scores diminish as students move up the educational ladder? Consider a parallel situation: Among all American and Canadian football linemen, body weight correlates with success. A 300-pound player tends to overwhelm a 200-pound opponent. But within the narrow 280- to 320-pound range typically found at the professional level, the correlation between weight and success becomes negligible (**FIGURE 61.4**). The narrower the *range* of weights, the lower the predictive power of body weight becomes. If an elite university takes only those students who have very high aptitude scores, those scores cannot possibly predict much. This will be true even if the test has excellent predictive validity with a more diverse sample of students. So, when we validate a test using a wide range of people but then use it with a restricted range of people, it loses much of its predictive validity.

Before You Move On

▶ ASK YOURSELF

Are you working to the potential reflected in your standardized test scores? What, other than your aptitude, is affecting your school performance?

▶ TEST YOURSELF

What was the purpose of Binet's pioneering intelligence test?

Answers to the Test Yourself questions can be found in Appendix E at the end of the book.

Module 61 Review

61-1

When and why were intelligence tests created?

- In the late 1800s, Francis Galton, who believed that genius was inherited, attempted but failed to construct a simple intelligence test.
- In France in 1904, Alfred Binet, who tended toward an environmental explanation of intelligence differences, started the modern intelligence-testing movement by developing questions to measure children's *mental age* and thus predict progress in the school system.
- During the early twentieth century, Lewis Terman of Stanford University revised Binet's work for use in the United States.
 - Terman believed intelligence is inherited, and he thought his *Stanford-Binet* could help guide people toward appropriate opportunities.
 - During this period, intelligence tests were sometimes used to "document" scientists' assumptions about the innate inferiority of certain ethnic and immigrant groups.

61-2 What's the difference between achievement and aptitude tests?

- *Achievement tests* are designed to assess what you have learned.
- *Aptitude tests* are designed to predict what you can learn.
- The *WAIS (Wechsler Adult Intelligence Scale)*, an aptitude test, is the most widely used intelligence test for adults.

61-3 What are standardization and the normal curve?

- *Standardization* establishes a basis for meaningful score comparisons by giving a test to a representative sample of future test-takers.
- The distribution of test scores often forms a *normal* (bell-shaped) *curve* around the central average score, with fewer and fewer scores at the extremes.

61-4 What are reliability and validity?

- *Reliability* is the extent to which a test yields consistent results (on two halves of the test, or when people are retested).
- *Validity* is the extent to which a test measures or predicts what it is supposed to.
 - A test has *content validity* if it samples the pertinent behavior (as a driving test measures driving ability).
 - It has *predictive validity* if it predicts a behavior it was designed to predict. (Aptitude tests have predictive ability if they can predict future achievements.)

Multiple-Choice Questions

1. A test-developer defines uniform testing procedures and meaningful scores by comparison with the performance of a pretested group. Which of the following best describes this process?
 - a. Reliability testing
 - b. Validation
 - c. Content validation
 - d. Standardization
 - e. Predictive validity
2. Which of the following best describes the extent to which a test yields consistent results upon retesting?
 - a. Content validity
 - b. Validity
 - c. Reliability
 - d. Predictive validity
 - e. Normal curve
3. Which of the following can be used to demonstrate that only about 2 percent of the population scores are at least two standard deviations above the mean on an intelligence test?
 - a. Reliability test
 - b. Aptitude test
 - c. Predictive validity test
 - d. Test-retest procedure
 - e. Normal curve

Practice FRQs

1. What are the fundamental differences between achievement and aptitude tests?
2. Name and briefly describe the three essential principals of test construction.

(3 points)

Answer

1 point: Achievement tests are designed to assess what a person has learned.

1 point: An aptitude test is designed to predict a person's future performance.

Module 62

The Dynamics of Intelligence

Module Learning Objectives

- 62-1** Describe the stability of intelligence scores over the life span.
- 62-2** Describe the traits of those at the low and high intelligence extremes.

We now can address some age-old questions about the dynamics of human intelligence—about its stability over the life span, and about the extremes of intelligence.

Stability or Change?

- 62-1** How stable are intelligence scores over the life span?

If we retested people periodically throughout their lives, would their intelligence scores be stable? Let's first explore the stability of mental abilities in later life.

Aging and Intelligence

What happens to our broader intellectual muscles as we age? Do they gradually decline, as does our body strength (even if relative intellectual and muscular strength in later life is predictable from childhood)? Or do they remain constant? The quest for answers to these questions illustrates psychology's self-correcting process. This research developed in phases.

PHASE I: CROSS-SECTIONAL EVIDENCE FOR INTELLECTUAL DECLINE

In *cross-sectional studies*, researchers at one point in time test and compare people of various ages. In such studies, researchers have consistently found that older adults give fewer correct answers on intelligence tests than do younger adults. WAIS-creator, David Wechsler (1972) therefore concluded that "the decline of mental ability with age is part of the general [aging] process of the organism as a whole." For a long time, this rather dismal view went unchallenged. Many corporations established mandatory retirement policies, assuming the companies would benefit by replacing aging workers with younger, presumably more capable, employees. As "everyone knows," you can't teach an old dog new tricks.

PHASE II: LONGITUDINAL EVIDENCE FOR INTELLECTUAL STABILITY

After colleges in the 1920s began giving intelligence tests to entering students, several psychologists saw their chance to study intelligence *longitudinally*. They retested the same **cohort**—the same group of people—over a period of years (Schaie & Geiwitz, 1982). What they found was a surprise: Until late in life, intelligence remained stable (**FIGURE 62.1** on the next page). On some tests, it even increased.

cohort a group of people from a given time period.

Figure 62.1**Cross-sectional versus longitudinal testing of intelligence at various ages**

In this test of one type of verbal intelligence (inductive reasoning), the cross-sectional method produced declining scores with age. The longitudinal method (in which the same people were retested over a period of years) produced a slight rise in scores well into adulthood. (Adapted from Schaie, 1994.)

How then are we to account for the cross-sectional findings? In retrospect, researchers saw the problem. When cross-sectional studies compared 70-year-olds and 30-year-olds, they compared people not only of two different ages but of two different eras. They compared generally less-educated people (born, say, in the early 1900s) with better-educated people (born after 1950), people raised in large families with people raised in smaller families, people growing up in less affluent families with people raised in more affluent families.

With this more optimistic view, the myth that intelligence sharply declines with age was laid to rest. At age 70, John Rock developed the birth control pill. At age 81—and 17 years

from the end of his college football coaching career—Amos Alonzo Stagg was named coach of the year. At age 89, architect Frank Lloyd Wright designed New York City's Guggenheim Museum. As “everyone knows,” given good health you're never too old to learn.

PHASE III: IT ALL DEPENDS

With “everyone knowing” two different and opposing facts about age and intelligence, something was clearly wrong. As it turns out, longitudinal studies have their own potential pitfalls. Those who survive to the end of longitudinal studies may be bright, healthy people whose intelligence is least likely to decline. (Perhaps people who died younger and were removed from the study had declining intelligence.) Adjusting for the loss of participants, as did a study following more than 2000 people over age 75 in Cambridge, England, reveals a steeper intelligence decline, especially after 85 (Brayne et al., 1999).

Research is further complicated by the finding that intelligence is not a single trait, but rather several distinct abilities. Intelligence tests that assess speed of thinking may place older adults at a disadvantage because of their slower neural processing. Meeting old friends on the street, names rise to the mind's surface more slowly—“like air bubbles in molasses,” said David Lykken (1999). But slower processing need not mean less intelligence. In four studies in which players were given 15 minutes to complete *New York Times* crossword puzzles, the highest average performance was achieved by adults in their fifties, sixties, and seventies (Salthouse, 2004). “Wisdom” tests assessing “expert knowledge about life in general and good judgment and advice about how to conduct oneself in the face of complex, uncertain circumstances” also suggested that older adults more than hold their own on such tasks (Baltes et al., 1993, 1994, 1999).

So the answers to our age-and-intelligence questions depend on what we assess and how we assess it. **Crystallized intelligence**—our accumulated knowledge as reflected in vocabulary and analogies tests—*increases* up to old age. **Fluid intelligence**—our ability to reason speedily and abstractly, as when solving novel logic problems—*decreases* beginning in the twenties and thirties, slowly up to age 75 or so, then more rapidly, especially after age 85 (Cattell, 1963; Horn, 1982; Salthouse, 2009). With age we lose and we win. We lose recall memory and processing speed, but we gain vocabulary knowledge (**FIGURE 62.2**). Our decisions also become less distorted by negative emotions such as anxiety, depression, and anger (Blanchard-Fields, 2007; Carstensen & Mikels, 2005). And despite their lesser fluid intelligence, older adults also show increased social reasoning, such as by taking multiple perspectives, appreciating knowledge limits, and thus offering helpful wisdom in times of social conflict (Grossman et al., 2010).

FYI

Like older people, older gorillas process information more slowly (Anderson et al., 2005).

“Knowledge is knowing a tomato is a fruit; wisdom is not putting it in a fruit salad.” -ANONYMOUS

crystallized intelligence our accumulated knowledge and verbal skills; tends to increase with age.

fluid intelligence our ability to reason speedily and abstractly; tends to decrease during late adulthood.

**Figure 62.2****With age we lose and we**

win Research reveals that word power grows with age, while fluid intelligence dimensions decline (Salthouse, 2010b).

Ann Baldwin/Shutterstock

These cognitive differences help explain why older adults are less likely to embrace new technologies (Charness & Boot, 2009). In 2010, only 31 percent of Americans ages 65 and older had broadband Internet at home, compared with 80 percent of adults under 30 (Pew, 2010). The age-related cognitive differences also help explain some curious findings about creativity. Mathematicians and scientists produce much of their most creative work during their late twenties or early thirties. In literature, history, and philosophy, people tend to produce their best work in their forties, fifties, and beyond—after accumulating more knowledge (Simonton, 1988, 1990). Poets, for example, who depend on fluid intelligence, reach their peak output earlier than prose authors, who need a deeper knowledge reservoir. This finding holds in every major literary tradition, for both living and dead languages.

Stability Over the Life Span

Now what about the stability of intelligence scores early in life? Except for extremely impaired or very precocious children, casual observation and intelligence tests before age 3 only modestly predict children's future aptitudes (Humphreys & Davey, 1988; Tasbihsazan et al., 2003). For example, children who are early talkers—speaking in sentences typical of 3-year-olds by age 20 months—are not especially likely to be reading by age 4½ (Crain-Thoreson & Dale, 1992). (A better predictor of early reading is having parents who have read lots of stories to their child.) Even Albert Einstein was slow in learning to talk (Quasha, 1980).

By age 4, however, children's performance on intelligence tests begins to predict their adolescent and adult scores. The consistency of scores over time increases with the age of the child. The remarkable stability of aptitude scores by late adolescence is seen in a U.S. Educational Testing Service® study of 23,000 students who took the SAT® exam and then later took the GRE® (Angoff, 1988). On either test, verbal scores correlated only modestly with math scores—revealing that these two aptitudes are distinct. Yet scores on the SAT® exam verbal test correlated +.86 with the scores on the GRE® verbal tests taken four to five years later. An equally astonishing +.86 correlation occurred between the two math tests. Given the time lapse and differing educational experiences of these 23,000 students, the stability of their aptitude scores is remarkable.

Ian Deary and his colleagues (2004, 2009) set a record for long-term follow-up. Their amazing longitudinal studies have been enabled by their country, Scotland, doing something that no nation has done before or since. On June 1, 1932, essentially every child in the country who had been born in 1921—87,498 children around age 11—was given an intelligence test. The aim was to identify working-class children who would benefit from

"In youth we learn, in age we understand." -MARIE VON EBNER-ESCHENBACH, *APHORISMS*, 1883

"My dear Adele, I am 4 years old and I can read any English book. I can say all the Latin substantives and adjectives and active verbs besides 52 lines of Latin poetry." -FRANCIS GALTON, LETTER TO HIS SISTER, 1827

FYI

Ironically, SAT® exam and GRE® scores correlate better with each other than either does with its intended criterion, school achievement. Thus, their reliability far exceeds their predictive validity. If either test was much affected by coaching, luck, or how one feels on the test day (as so many people believe), such reliability would be impossible.

Figure 62.3

Intelligence endures When Ian Deary and his colleagues (2004) retested 80-year-old Scots, using an intelligence test they had taken as 11-year-olds, their scores across seven decades correlated $+0.66$. (When 207 survivors were again retested at age 87, the correlation with their age 11 scores was $+0.51$ [Gow et al., 2011].)

“Whether you live to collect your old-age pension depends in part on your IQ at age 11.”

—IAN DEARY, “INTELLIGENCE, HEALTH, AND DEATH,” 2005

further education. Sixty-five years later to the day, Patricia Whalley, the wife of Deary’s co-worker, Lawrence Whalley, discovered the test results on dusty storeroom shelves at the Scottish Council for Research in Education, not far from Deary’s Edinburgh University office. “This will change our lives,” Deary replied when Whalley told him the news.

And so it has, with dozens of studies of the stability and the predictive capacity of these early test results. For example, when the intelligence test administered to 11-year-old Scots in 1932 was readministered to 542 survivors as turn-of-the-millennium 80-year-olds, the correlation between the

two sets of scores—after almost 70 years of varied life experiences—was striking (**FIGURE 62.3**). A later study that followed Scots born in 1936 from ages 11 to 70 confirmed the remarkable stability of intelligence, independent of life circumstance (Johnson et al., 2010).

High-scoring 11-year-olds also were more likely to be living independently as 77-year-olds and were less likely to have suffered the cognitive erosion of Alzheimer’s disease (Starr et al., 2000; Whalley et al., 2000). Among girls scoring in the highest 25 percent, 70 percent were still alive at age 76—as were only 45 percent of those scoring in the lowest 25 percent (**FIGURE 62.4**). (World War II prematurely ended the lives of many of the male test-takers.) Follow-up studies with other large samples confirm the phenomenon: More intelligent children and adults live healthier and longer (Deary et al., 2008, 2010; Der et al., 2009; Weiss et al., 2009). One study that followed 93 nuns found that those exhibiting less verbal ability in essays written when entering convents in their teens were more at risk for Alzheimer’s disease after age 75 (Snowdon et al., 1996).

Pause a moment: Have you any ideas why more intelligent people might live longer? Deary (2008) reports four possible explanations:

1. Intelligence facilitates more education, better jobs, and a healthier environment.
2. Intelligence encourages healthy living: less smoking, better diet, more exercise.
3. Prenatal events or early childhood illnesses might have influenced both intelligence and health.
4. A “well-wired body,” as evidenced by fast reaction speeds, perhaps fosters both intelligence and longevity.

Figure 62.4

Living smart Women scoring in the highest 25 percent on the Scottish national intelligence test at age 11 tended to live longer than those who scored in the lowest 25 percent. (From Whalley & Deary, 2001.)

Extremes of Intelligence

62-2 What are the traits of those at the low and high intelligence extremes?

One way to glimpse the validity and significance of any test is to compare people who score at the two extremes of the normal curve. The two groups should differ noticeably, and they do.

The Low Extreme

At one extreme of the normal curve are those with unusually low intelligence test scores. To be labeled as having an **intellectual disability** (formerly referred to as *mental retardation*), a person must have both a low test score and difficulty adapting to the normal demands of independent living. American Association on Intellectual and Developmental Disabilities guidelines specify performance that is approximately two standard deviations below average (Schalock et al., 2010). For an intelligence test with 100 as average and a standard deviation of 15, that means (allowing for some variation in one's test score) an IQ of approximately 70 or below. The second criterion is a comparable limitation in adaptive behavior as expressed in

- *conceptual skills*, such as language, literacy, and concepts of money, time, and number,
- *social skills*, such as interpersonal skills, social responsibility, and the ability to follow basic rules and laws and avoid being victimized, and
- *practical skills*, such as daily personal care, occupational skill, and travel and health care.

Intellectual disability is a developmental condition that is apparent before age 18, sometimes with a known physical cause. **Down syndrome**, for example, is a disorder of varying severity caused by an extra chromosome 21 in the person's genetic makeup.

Consider one reason why people diagnosed with a mild intellectual disability—those just below the 70 score—might be better able to live independently today than many decades ago, when they were institutionalized. Recall that, thanks to the Flynn effect, the tests have been periodically restandardized. As that happened, individuals who scored near 70 on earlier tests suddenly lost about 6 IQ points. Two people with the same ability level could thus be classified differently, depending on when they were tested (Kanaya et al., 2003; Reynolds et al., 2010). As the boundary shifts, more people become eligible for special education and for Social Security payments for those with an intellectual disability. And in the United States (one of only a few industrialized countries with the death penalty), fewer people are eligible for execution—the U.S. Supreme Court ruled in 2002 that the execution of people with an intellectual disability is “cruel and unusual punishment.” For people near that score of 70, intelligence testing can be a high-stakes competition. And so it was for Teresa Lewis, a “dependant personality” with limited intellect, who was executed by the state of Virginia in 2010. Lewis, whose reported IQ score was 72, reportedly agreed to a plot in which two men killed her husband and stepson in exchange for a split of a life insurance payout (Eckholm, 2010). If only she had scored 69.

The High Extreme

In one famous project begun in 1921, Lewis Terman studied more than 1500 California schoolchildren with IQ scores over 135. Contrary to the popular notion that intellectually gifted children are frequently maladjusted, Terman's high-scoring children, like those in later studies, were healthy, well-adjusted, and unusually successful academically (Koenen et al., 2009; Lubinski, 2009a; Stanley, 1997). When restudied over the next seven decades, most people in Terman's group (the “Termites”) had attained high levels of education (Austin et al., 2002; Holahan & Sears, 1995). They included many doctors, lawyers, professors, scientists, and writers, but no Nobel Prize winners.

intellectual disability a condition of limited mental ability, indicated by an intelligence score of 70 or below and difficulty in adapting to the demands of life. (Formerly referred to as *mental retardation*.)

Down syndrome a condition of mild to severe intellectual disability and associated physical disorders caused by an extra copy of chromosome 21.

Reuters/Claudia Daut

Mainstreaming in Chile Most Chilean children with Down syndrome attend separate schools for children with special needs. However, this boy is a student at the Altamira School, where children with differing abilities share the classrooms.

FYI

Terman did test two future Nobel laureates in physics but they failed to score above his gifted sample cutoff (Hulbert, 2005).

The extremes of intelligence

Moshe Kai Cavalin completed his third college degree by the time he was 14, when the math major graduated from UCLA. According to his mother, he first picked up a college textbook and started reading it at age 2.

“Joining Mensa means that you are a genius. . . . I worried about the arbitrary 132 cutoff point, until I met someone with an IQ of 131 and, honestly, he was a bit slow on the uptake.” -COMEDIAN STEVE MARTIN, 1997

A more recent study of precocious youths who aced the math SAT® exam at age 13—by scoring in the top quarter of 1 percent of their age group—were at age 33 twice as likely to have patents as were those in the bottom quarter of the top 1 percent (Wai et al., 2005). Compared with the math aces, 13-year-olds scoring high on verbal aptitude were more likely to have become humanities professors or written a novel (Park et al., 2007). About 1 percent of Americans earn doctorates. But among those scoring in the top 1 in 10,000—on the mere two-hour SAT® at age 12 or 13—more than half have done so (Lubinski, 2009b).

These whiz kids remind me of Jean Piaget, who by age 15 was publishing scientific articles on mollusks and who went on to become the twentieth century’s most famous developmental psychol-

ogist (Hunt, 1993). Children with extraordinary academic gifts are sometimes more isolated, introverted, and in their own worlds (Winner, 2000). But most thrive.

Is there a gifted education program at your school? There are critics who question many of the assumptions of currently popular “talented and gifted child” programs, such as the belief that only 3 to 5 percent of children are gifted and that it pays to identify and “track” these special few—segregating them in special classes and giving them academic enrichment not available to their peers. Critics note that tracking by aptitude sometimes creates a self-fulfilling prophecy: Those implicitly labeled “ungifted” may be influenced to become so (Lipsey & Wilson, 1993; Slavin & Braddock, 1993). Denying lower-ability students opportunities for enriched education can widen the achievement gap between ability groups and increase their social isolation from one another (Carnegie, 1989; Stevenson & Lee, 1990). Because minority and low-income youth are more often placed in lower academic groups, tracking can also promote segregation and prejudice—hardly, note critics, a healthy preparation for working and living in a multicultural society.

Critics and proponents of gifted education do, however, agree on this: Children have differing gifts, whether at math, verbal reasoning, art, or social leadership. Educating children as if all were alike is as naive as assuming that giftedness is something, like blue eyes, that you either have or do not have. One need not hang labels on children to affirm their special talents and to challenge them all at the frontiers of their own ability and understanding. By providing *appropriate developmental placement* suited to each child’s talents, we can promote both equity and excellence for all (Colangelo et al., 2004; Lubinski & Benbow, 2000; Sternberg & Grigorenko, 2000).

Before You Move On

▶ ASK YOURSELF

How do you feel about mainstreaming children of all ability levels in the same classroom? What evidence are you using to support your view?

▶ TEST YOURSELF

The Smiths have enrolled their 2-year-old son in a special program that promises to assess his IQ and, if he places in the top 5 percent of test-takers, to create a plan that will guarantee his admission to a top university at age 18. Why is this endeavor of questionable value?

Answers to the Test Yourself questions can be found in Appendix E at the end of the book.

Module 62 Review

62-1 How stable are intelligence scores over the life span?

- Cross-sectional studies (comparing people of different ages) and longitudinal studies (retesting the same *cohort* over a period of years) have shown that *fluid intelligence* declines in older adults, in part because neural processing slows. *Crystallized intelligence* tends to increase.
- The stability of intelligence test scores increases with age.
 - At age 4, scores fluctuate somewhat but begin to predict adolescent and adult scores.
 - By early adolescence, scores are very stable and predictive.

62-2 What are the traits of those at the low and high intelligence extremes?

- An intelligence test score of or below 70 is one diagnostic criterion for the diagnosis of *intellectual disability* (others are limited conceptual, social, and practical skills). People with this diagnosis vary from near-normal to requiring constant aid and supervision.
- *Down syndrome* is a developmental disorder caused by an extra copy of chromosome 21.
- High-scoring people tend to be healthy and well-adjusted, as well as unusually successful academically.
 - Schools sometimes “track” such children, separating them from students with lower scores. Such programs can become self-fulfilling prophecies as both groups live up to—or down to—others’ perceptions and expectations.

Multiple-Choice Questions

- Which of the following is a longitudinal study?
 - Researchers test the intelligence of all the students in a high school.
 - Intelligence tests are given to the residents of a nursing home.
 - Researchers randomly select 50 students from a high school with 2000 students. The 50 students are given intelligence tests.
 - A group of college juniors is given an extensive battery of tests over a period of 2 days.
 - A group of kindergartners is given an intelligence test. They are retested every other year for 30 years.
- Which of the following best represents crystallized intelligence?
 - Jake can solve math word problems quickly.
 - Grandpa Milt is good at crossword puzzles.
 - Aliyah has a knack for training dogs.
 - Anna writes creative computer programs.
 - Heng bakes excellent chocolate chip cookies.
- Who conducted a famous study of high IQ children?

a. Lewis Terman	d. Howard Gardner
b. David Wechsler	e. Alfred Binet
c. Robert Sternberg	
- Intellectual disability is defined by both IQ and which of the following?

a. Chronological age	d. Physical condition
b. Mental age	e. Heritability
c. Adaptive ability	

Practice FRQs

- Name and describe the two main types of evidence used to determine whether there is an intellectual decline as people age.
- Explain three reasons why more intelligent people might live longer.
(3 points)

Answer

2 points: Cross-sectional evidence, which comes from studies that examine several age groups at once.

2 points: Longitudinal evidence, which comes from studies that examine the same group of people over a long period of time.

Module 63

Studying Genetic and Environmental Influences on Intelligence

Module Learning Objectives

- 63-1** Discuss the evidence for a genetic influence on intelligence, and explain what is meant by heritability.
- 63-2** Discuss the evidence for environmental influences on intelligence.

Terra Images/AP Images

63-1 What evidence points to a genetic influence on intelligence, and what is heritability?

Intelligence runs in families. But why? Are our intellectual abilities mostly inherited? Or are they molded by our environment?

Few issues arouse such passion or have such serious political implications. Consider: If we mainly inherit our differing mental abilities, and if success reflects those abilities, then people's socioeconomic standing will correspond to their inborn differences. This could lead to those on top believing their intellectual birthright justifies their social positions.

But if mental abilities are primarily nurtured by our environments, then children from disadvantaged environments can expect to lead disadvantaged lives. In this case, people's standing will result from their unequal opportunities.

For now, as best we can, let's set aside such political implications and examine the evidence.

Twin and Adoption Studies

Do people who share the same genes also share mental abilities? As you can see from **FIGURE 63.1**, which summarizes many studies, the answer is clearly *Yes*. Consider:

- The intelligence test scores of identical twins raised together are virtually as similar as those of the same person taking the same test twice (Lykken, 1999; Plomin, 2001). (The scores of fraternal twins, who share only about half their genes, are much less similar.) Estimates of the **heritability** of intelligence—the extent to which intelligence test score variation can be attributed to genetic variation—range from 50 to 80 percent (Johnson et al., 2009; Neisser et al., 1996; Plomin, 2003). Identical twins also exhibit substantial similarity (and heritability) in specific talents, such as music, math, and sports (Vinkhuyzen et al., 2009).
- Brain scans reveal that identical twins' brains are built and function similarly. They have similar gray and white matter volume (Deary et al., 2009). Their brains (unlike those of fraternal twins) are virtually the same in areas associated with verbal and spatial intelligence (Thompson et al., 2001). And their brains show similar activity while doing mental tasks (Koten et al., 2009).

Figure 63.1

Intelligence: Nature and nurture The most genetically similar people have the most similar intelligence scores. Remember: 1.0 indicates a perfect correlation; zero indicates no correlation at all. (Data from McGue et al., 1993.)

- Are there known genes for genius? Today's researchers have identified chromosomal regions important to intelligence, and they have pinpointed specific genes that seemingly influence variations in intelligence and learning disorders (Dick, 2007; Plomin & Kovas, 2005; Posthuma & de Geus, 2006). But intelligence appears to be *polygenic*, involving many genes, with each gene accounting for much less than 1 percent of intelligence variations (Butcher et al., 2008). Intelligence is like height, suggests Wendy Johnson (2010): 54 specific gene variations together have accounted for 5 percent of our individual differences in height, leaving the rest yet to be discovered. Do we really need to discover them all—or is it enough to know that few individual genes have a big effect on height, or intelligence? What matters is the combination of many genes.

Other evidence points to the effects of environment. Twin studies show some environmental contribution to IQ score variation among top scorers (Brant et al., 2009; Kirkpatrick et al., 2009). Where environments vary widely, as they do among children of less-educated parents, environmental differences are more predictive of intelligence scores (Rowe et al., 1999; Tucker-Drob et al., 2011; Turkheimer et al., 2003). Studies also show that adoption enhances the intelligence scores of mistreated or neglected children (van IJzendoorn & Juffer, 2005, 2006).

Seeking to disentangle genes and environment, researchers have compared the intelligence test scores of adopted children with those of (a) their adoptive siblings, (b) their biological parents (the providers of their genes), and (c) their adoptive parents, the providers of their home environment. During childhood, the intelligence test scores of adoptive siblings correlate modestly. Over time, adopted children accumulate experience in their differing adoptive families. So would you expect the family-environment effect to grow with age and the genetic-legacy effect to shrink?

If you would, behavior geneticists have a stunning surprise for you. Mental similarities between adopted children and their adoptive families wane with age, until the correlation approaches zero by adulthood (McGue et al., 1993). Genetic influences—not environmental ones—become more apparent as we accumulate life experience. Identical twins' similarities, for example, continue or increase into their eighties. Thus, report Ian Deary and his colleagues (2009), the heritability of general intelligence increases from “about 30 percent” in early childhood to “well over 50 percent in adulthood.” In one massive study of 11,000 twin pairs in four

AP® Exam Tip

Figure 63.1 is worth spending some time on. Try grabbing a study buddy and explaining whether each of the five conditions provides more support for nature or more for nurture. In most cases, it's some of each and you have to look at comparisons between categories to really be able to draw conclusions.

“Selective breeding has given me an aptitude for the law, but I still love fetching a dead duck out of freezing water.”

Figure 63.2**Who do adopted children resemble in verbal ability?**

As the years went by in their adoptive families, children's verbal ability scores became modestly more like their *biological* parents' scores. (Adapted from Plomin & DeFries, 1998.)

“There are more studies addressing the genetics of *g* [general intelligence] than any other human characteristic.”
-ROBERT PLOMIN (1999)

countries, the heritability of *g* increased from 41 percent in middle childhood to 55 percent in adolescence to 66 percent in young adulthood (Haworth et al., 2010). Similarly, adopted children's verbal ability scores over time become more like those of their biological parents (**FIGURE 63.2**). Who would have guessed?

Environmental Influences

63-2 What does evidence reveal about environmental influences on intelligence?

Genes make a difference. Even if we were all raised in the same intellectually stimulating environment, we would have differing aptitudes. But life experiences also matter. Human environments are rarely as impoverished as the dark and barren cages inhabited by deprived rats that develop thinner-than-normal brain cortexes (see Module 50). Yet severe deprivation also leaves footprints on the human brain.

Early Environmental Influences

Nowhere is the intertwining of biology and experience more apparent than in impoverished human environments such as J. McVicker Hunt (1982) observed in a destitute Iranian orphanage. The typical child Hunt observed there could not sit up unassisted at age 2 or walk at age 4. The little care the infants received was not in response to their crying, cooing, or other behaviors, so the children developed little sense of personal control over their environment.

They were instead becoming passive “glum lumps.” Extreme deprivation was bludgeoning native intelligence—a finding confirmed by other studies of children raised in poorly run orphanages in Romania and elsewhere (Nelson, et al., 2009; van IJzendoorn et al., 2008).

Aware of both the dramatic effects of early experiences and the impact of early intervention, Hunt began a program of *tutored human enrichment*. He trained caregivers to play language-fostering games with 11 infants, imitating the babies' babbling, then engaging them in vocal follow-the-leader, and finally teaching them sounds from the Persian language. The results were dramatic. By 22 months of age,

Devastating neglect

Some Romanian orphans, such as this child in the Leaganul Pentru Copii orphanage in 1990, had minimal interaction with caregivers, and suffered delayed development.

Josef Pohlross/The Image Works

the infants could name more than 50 objects and body parts, and so charmed visitors that most were adopted—an unprecedented success for the orphanage.

Hunt's findings are an extreme case of a more general finding: Among those economically impoverished, environmental conditions can depress cognitive development. Schools with many poverty-level children often have less-qualified teachers, as one study of 1450 Virginia schools found. So these children may receive a less-enriched education. And even after controlling for poverty, having less-qualified teachers predicted lower achievement scores (Tuerk, 2005). Malnutrition also plays a role. Relieve infant malnutrition with nutritional supplements, and poverty's effect on physical and cognitive development lessens (Brown & Pollitt, 1996).

Do studies of such early interventions indicate that providing an “enriched” environment can “give your child a superior intellect,” as some popular products claim? Most experts are doubtful (Bruer, 1999). Although malnutrition, sensory deprivation, and social isolation can retard normal brain development, there is no environmental recipe for fast-forwarding a normal infant into a genius. All babies should have normal exposure to sights, sounds, and speech. Beyond that, Sandra Scarr's (1984) verdict still is widely shared: “Parents who are very concerned about providing special educational lessons for their babies are wasting their time.”

Still, explorations of intelligence promotion continue. Some parents, after exposing their 12- to 18-month-old babies to educational DVDs such as from the *Baby Einstein* series, have observed their baby's vocabulary growing. To see whether such cognitive growth is a result of the DVD exposure, or simply of infants' natural language explosion, two research teams assigned babies to DVD exposure or a control group (DeLoache et al., 2010; Reichert et al., 2010). Their common finding: The two groups' word-learning did not differ.

Schooling and Intelligence

Later in childhood, schooling is one intervention that pays intelligence score dividends. Schooling and intelligence interact, and both enhance later income (Ceci & Williams, 1997, 2009). Hunt was a strong believer in the ability of education to boost children's chances for success by developing their cognitive and social skills. Indeed, his 1961 book, *Intelligence and Experience*, helped launch Project Head Start in 1965, a U.S. government-funded preschool program that serves more than 900,000 children, most of whom come from families below the poverty level (Head Start, 2010). Does it succeed? Generally, the aptitude benefits dissipate over time (reminding us that life experience *after* Head Start matters, too). Psychologist Edward Zigler, the program's first director, nevertheless believed there are long-term benefits (Ripple & Zigler, 2003; Zigler & Styfco, 2001).

Genes and experience together weave the intelligence fabric. (Recall from Module 14 that *epigenetics* is one field that studies this nature–nurture meeting place.) But what we accomplish with our intelligence depends also on our own beliefs and motivation. One analysis of 72,431 collegians found that study motivation and study skills rivaled previous grades and aptitude as predictors of academic achievement (Credé & Kuncel, 2008). Motivation even affects intelligence test performance. Four dozen studies show that, when promised money for doing well, adolescents score higher (Duckworth et al., 2011).

Psychologist Carol Dweck (2006, 2007, 2008) reports that believing intelligence is biologically set and unchanging can lead to a “fixed mindset.” Believing intelligence is changeable, a “growth mindset” results in a focus on learning and growing. As collegians, these believers also tend to happily flourish (Howell, 2009). Dweck has developed interventions that effectively teach young teens that the brain is like a muscle that grows stronger with use as neuron connections grow. Indeed, as we noted earlier, superior achievements in fields from sports to science to music arise from disciplined effort and sustained practice (Ericsson et al., 2007).

Before You Move On

▶ ASK YOURSELF

How have genetic and environmental influences shaped your intelligence?

▶ TEST YOURSELF

As society succeeds in creating equality of opportunity, it will also increase the heritability of ability. The heritability of intelligence scores will be greater in a society marked by equal opportunity than in a society of peasants and aristocrats. Why?

Answers to the Test Yourself questions can be found in Appendix E at the end of the book.

Module 63 Review

63-1

What evidence points to a genetic influence on intelligence, and what is heritability?

- Studies of twins, family members, and adoptees indicate a significant hereditary contribution to intelligence scores.
- Intelligence seems to be polygenetic, and researchers are searching for genes that exert an influence.
- *Heritability* is the proportion of variation among individuals that can be attributed to genes.

63-2

What does evidence reveal about environmental influences on intelligence?

- Studies of twins, family members, and adoptees also provide evidence of environmental influences.
- Test scores of identical twins raised apart are slightly less similar (though still very highly correlated) than the scores of identical twins raised together.
- Studies of children raised in extremely impoverished environments with minimal social interaction indicate that life experiences can significantly influence intelligence test performance.
- No evidence supports the idea that normal, healthy children can be molded into geniuses by growing up in an exceptionally enriched environment.

Multiple-Choice Questions

- Heritability relates to the
 - percentage of a person's intelligence that is due to environmental influences.
 - percentage of a person's intelligence that is due to genetics.
 - correlation of intelligence test scores among family members.
 - extent to which variability among individuals' intelligence scores can be attributed to genetic variation.
 - genetic stability of intelligence over time.
- The correlation between the IQ scores of fraternal twins raised together is lower than IQ scores of identical twins raised together. What conclusion can be drawn from this data?
 - Nothing, because the type of twin has not been held constant.
 - Nothing, because there is no comparison between twins and adopted children.
 - Nothing, because cultural differences have not been considered.
 - There is a genetic effect on intelligence.
 - There is an environmental effect on intelligence.

- 3.** Which of the following is true of the mental similarities between adoptive children and their adoptive parents as they age?
- Adoptive children become much more similar to their adoptive families over time.
 - Adoptive children become slightly more similar to their adoptive families over time.
 - There is hardly any similarity, either when the adoptive children are young or when they are older.
 - Adoptive children become slightly less similar to their adoptive families over time.
 - Adoptive children become much less similar to their adoptive families over time.
- 4.** According to Carol Dweck, students are often hampered by a “fixed mindset.” This means they believe:
- intelligence is biologically set and unchangeable.
 - it is never good to change your mind once it is made up.
 - intelligence can be “repaired” by doing specific mental exercises.
 - they have already done everything they can to improve.
 - problems can only be solved a particular way.

Practice FRQs

- 1.** Explain two environmental interventions that might help poverty-level schoolchildren develop better cognitive skills.

Answer

1 point: The presence of more highly qualified teachers is positively correlated with higher student achievement.

1 point: Nutritional supplements can help alleviate the effects of the poor nutrition that often accompanies economic poverty.

- 2.** Explain whether each of the following comparisons indicates a greater influence of genetics on intelligence or a greater influence of environment on intelligence.
- The correlation of intelligence test scores for identical twins raised *together* is about +.85. For identical twins raised *apart*, the correlation is about +.72.
 - The correlation of intelligence scores for identical twins raised together is about +.85. For fraternal twins raised together, it is about +.60.

(2 points)

Module 64

Group Differences and the Question of Bias

Module Learning Objectives

- 64-1** Describe how and why the genders differ in mental ability scores.
- 64-2** Describe how and why racial and ethnic groups differ in mental ability scores.
- 64-3** Discuss whether intelligence tests are inappropriately biased.

Group Differences in Intelligence Test Scores

If there were no group differences in aptitude scores, psychologists could politely debate hereditary and environmental influences in their ivory towers. But there are group differences. What are they? And what shall we make of them?

Gender Similarities and Differences

- 64-1** How and why do the genders differ in mental ability scores?

In science, as in everyday life, differences, not similarities, excite interest. Compared with the anatomical and physiological similarities between men and women, our differences are minor. In that 1932 testing of all Scottish 11-year-olds, for example, girls' average intelligence score was 100.6 and boys' was 100.5 (Deary et al., 2003). So far as *g* is concerned, boys and girls, men and women, are the same species.

Yet, most people find differences more newsworthy. Girls are better spellers, more verbally fluent, better at locating objects, better at detecting emotions, and more sensitive to touch, taste, and color (Halpern et al., 2007). Boys outperform girls in tests of spatial ability and complex math problems, though in math computation and overall math performance, boys and girls hardly differ (Else-Quest et al., 2010; Hyde & Mertz, 2009; Lindberg et al., 2010). Males' mental ability scores also vary more than females'. Thus, boys worldwide outnumber girls at both the low extreme and the high extreme (Machin & Pekkarinen, 2008; Strand et al., 2006). Boys, for example, are more often found in special education classes. And among 12- to 14-year-olds scoring extremely high (700 or higher) on the SAT® exam math section, boys outnumber girls 4 to 1 (Wai et al., 2010).

The most reliable male edge appears in spatial ability tests like the one shown in **FIGURE 64.1**. The solution requires speedily rotating three-dimensional objects in one's mind (Collins & Kimura, 1997; Halpern, 2000). Today, such skills help when fitting suitcases into a car trunk, playing chess, or doing certain types of geometry problems. From an evolutionary perspective, those same skills would have helped our ancestral fathers track prey and make their way home (Geary, 1995, 1996; Halpern et al., 2007). The survival of our ancestral mothers may have benefited more from a keen memory for the location of edible plants—a legacy that lives today in women's superior memory for objects and their location.

But experience also matters. One experiment found that playing action video games boosts spatial abilities (Feng et al., 2007). And you probably won't be surprised to know that among entering American collegians, six times as many men (23 percent) as women (4 percent) report playing video/computer games six or more hours a week (Pryor et al., 2010).

Evolutionary psychologist Steven Pinker (2005) argues that biological as well as social influences appear to affect gender differences in life priorities (women's greater interest in people versus men's in money and things), in risk-taking (with men more reckless), and in math reasoning and spatial abilities. Such differences are, he notes, observed across cultures, stable over time, influenced by prenatal hormones, and observed in genetic boys raised as girls. Culturally influenced preferences also help explain women selecting people—rather than math-intensive vocations (Ceci & Williams, 2010, 2011).

Other critics urge us to remember that social expectations and divergent opportunities shape boys' and girls' interests and abilities (Crawford et al., 1995; Eccles et al., 1990). Gender-equal cultures, such as Sweden and Iceland, exhibit little of the gender math gap found in gender-unequal cultures, such as Turkey and Korea (Guiso et al., 2008).

Nature or nurture? At this 2005 Google Inc.-sponsored computer coding competition, programmers competed for cash prizes and possible jobs. What do you think accounted for the fact that only one of the 100 finalists was female?

Racial and Ethnic Similarities and Differences

64-2 How and why do racial and ethnic groups differ in mental ability scores?

Fueling the group-differences debate are two other disturbing but agreed-upon facts:

- Racial groups differ in their average intelligence test scores.
- High-scoring people (and groups) are more likely to attain high levels of education and income.

There are many group differences in average intelligence test scores. New Zealanders of European descent outscore native Maori New Zealanders. Israeli Jews outscore Israeli Arabs. Most Japanese outscore most Burakumin, a stigmatized Japanese minority. Those who can hear outscore those born deaf (Braden, 1994; Steele, 1990; Zeidner, 1990). And White Americans have outsourced Black Americans. This Black-White difference has diminished somewhat in recent years, especially among children (Dickens & Flynn, 2006; Nisbett, 2009). Such *group* differences provide little basis for judging individuals. Worldwide, women outlive men by 4 years, but knowing only that you are male or female won't tell us much about how long you will live.

We have seen that heredity contributes to *individual* differences in intelligence. But group differences in a heritable trait may be entirely environmental. Consider one of nature's experiments: Allow some children to grow up hearing their culture's dominant language, while others, born deaf, do not. Then give both groups an intelligence test rooted in

© Larry Williams/CORBIS

the dominant language, and (no surprise) those with expertise in that language will score highest. Although individual performance differences may be substantially genetic, the group difference is not (**FIGURE 64.2**).

Might the racial gap be similarly environmental? Consider:

Genetics research reveals that under the skin, the races are remarkably alike. The average genetic difference between two Icelandic villagers or between two Kenyans greatly exceeds the group difference between Icelanders and Kenyans (Cavalli-Sforza et al., 1994; Rosenberg et al., 2002). Moreover, looks can deceive. Light-skinned Europeans and dark-skinned Africans are genetically closer than are dark-skinned Africans and dark-skinned Aboriginal Australians.

Race is not a neatly defined biological category. Some scholars argue that there is a reality to race, noting that there are genetic markers for race (the continent of one's ancestry), that medical risks (such as skin cancer or high blood pressure) vary by race, and that most people self-identify with a given race (Hunt & Carlson, 2007). Behavioral traits may also vary by race. "No runner of Asian or European descent—a majority of the world's population—has broken 10 seconds in the 100-meter dash, but dozens of runners of West African descent have done so," observed psychologist David Rowe (2005). Many social scientists, though, see race primarily as a social construction without well-defined physical boundaries, as each race blends seamlessly into the race of its geographical neighbors (Helms et al., 2005; Smedley & Smedley, 2005). People with varying ancestry may categorize themselves in the same race. Moreover, with increasingly mixed ancestries, more and more people defy neat racial categorization and self-identify as multiracial (Pauker et al., 2009).

The intelligence test performance of today's better-fed, better-educated, and more test-prepared population exceeds that of the 1930s population—by a greater margin than the intelligence test score of the average White today exceeds that of the average Black. One research review noted that the average IQ test performance of today's sub-Saharan Africans is the same as Brit-

Figure 64.2

Group differences and environmental impact

Even if the variation between members within a group reflects genetic differences, the average difference between groups may be wholly due to the environment. Imagine that seeds from the same mixture are sown in different soils. Although height differences *within* each window box will be genetic, the height difference *between* the two groups will be environmental. (From Lewontin, 1976.)

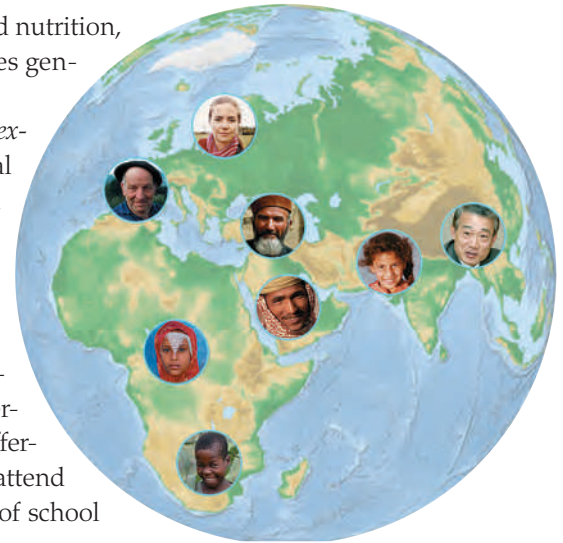

ish adults in 1948, with the possibility of similar gains to come, given improved nutrition, economic development, and education (Wicherts et al., 2010). No one attributes generational group differences to genetics.

When Blacks and Whites have or receive the same pertinent knowledge, they exhibit similar information-processing skill. “The data support the view that cultural differences in the provision of information may account for racial differences in IQ,” report researchers Joseph Fagan and Cynthia Holland (2007).

Schools and culture matter. Countries whose economies create a large wealth gap between rich and poor tend also to have a large rich/poor IQ gap (Nisbett, 2009). Moreover, educational policies such as kindergarten attendance, school discipline, and instructional time per year predict national differences in intelligence and knowledge tests (Rindermann & Ceci, 2009). Asian students outperform North American students on math achievement and aptitude tests. This difference may reflect conscientiousness more than competence. Asian students also attend school 30 percent more days per year and spend much more time in and out of school studying math (Geary et al., 1996; Larson & Verma, 1999; Stevenson, 1992).

In different eras, different ethnic groups have experienced golden ages—periods of remarkable achievement. Twenty-five-hundred years ago, it was the Greeks and the Egyptians, then the Romans; in the eighth and ninth centuries, genius seemed to reside in the Arab world; 500 years ago it was the Aztec Indians and the peoples of Northern Europe. Today, people marvel at Asians’ technological genius and Jews’ cultural success. In today’s United States, Jews are 2 percent of the population, 21 percent of Ivy League student bodies, 37 percent of Academy Award–winning directors, and 51 percent of Pulitzer Prize winners for nonfiction; worldwide, they have been 27 percent of Nobel physics laureates and 54 percent of world chess champions (Brooks, 2010). Cultures rise and fall over centuries; genes do not. That fact makes it difficult to attribute a natural superiority to any race.

Moreover, consider the striking results of a national study that looked back over the mental test performances of White and Black young adults after graduation from college. From eighth grade through the early high school years, the average aptitude score of the White students increased, while that of the Black students decreased—creating a gap that reached its widest point at about the time that high school students like you take college admissions tests. But during college, the Black students’ scores increased “more than four times as much” as those of their White counterparts, thus greatly decreasing the aptitude gap. “It is not surprising,” concluded researcher Joel Myerson and his colleagues (1998), “that as Black and White students complete more grades in high school environments that differ in quality, the gap in cognitive test scores widens. At the college level, however, where Black and White students are exposed to educational environments of comparable quality . . . many Blacks are able to make remarkable gains, closing the gap in test scores.”

Nature’s own morphing Nature draws no sharp boundaries between races, which blend gradually one into the next around the Earth. Thanks to the human urge to classify, however, people socially define themselves in racial categories, which become catchall labels for physical features, social identity, and nationality.

“Do not obtain your slaves from Britain, because they are so stupid and so utterly incapable of being taught.” -CICERO, 106–43 B.C.E.

The Question of Bias

64-3 Are intelligence tests inappropriately biased?

If one assumes that race is a meaningful concept, the debate over race differences in intelligence divides into three camps, note Earl Hunt and Jerry Carlson (2007):

- There are genetically disposed race differences in intelligence.
- There are socially influenced race differences in intelligence.
- There are race differences in test scores, but the tests are inappropriate or biased.

Are intelligence tests biased? The answer depends on which of two very different definitions of *bias* we use.

Two Meanings of Bias

We consider a test biased if it detects not only innate differences in intelligence but also performance differences caused by cultural experiences. This in fact happened to Eastern European immigrants in the early 1900s. Lacking the experience to answer questions about their new culture, many were classified as feeble-minded.

In this popular sense, intelligence tests are biased. They measure your developed abilities, which reflect, in part, your education and experiences. You may have read examples of intelligence test items that make middle-class assumptions (for example, that a cup goes with a saucer). Do such items bias the test against those who do not use saucers? Could such questions explain racial differences in test performance? If so, are tests a vehicle for discrimination, consigning potentially capable children, some of whom may have a different native language, to dead-end classes and jobs? And could creating culture-neutral questions—such as by assessing people’s ability to learn novel words, sayings, and analogies—enable culture-fair aptitude tests (Fagan & Holland, 2007, 2009)?

Defenders of the existing aptitude tests note that racial group differences persist on nonverbal items, such as counting digits backward (Jensen, 1983, 1998). Moreover, they add, blaming the test for a group’s lower scores is like blaming a messenger for bad news. Why blame the tests for exposing unequal experiences and opportunities? If, because of malnutrition, people were to suffer stunted growth, would you blame the measuring stick that reveals it? If unequal past experiences predict unequal future achievements, a valid aptitude test will detect such inequalities.

The second meaning of *bias*—its *scientific* meaning—is different. It hinges on a test’s validity—on whether it predicts future behavior only for some groups of test-takers. For example, if the SAT® exam accurately predicted the college achievement of women but not that of men, then the test would be biased. In this statistical meaning of the term, the near-consensus among psychologists (as summarized by the U.S. National Research Council’s Committee on Ability Testing and the American Psychological Association’s Task Force on Intelligence) is that the major U.S. aptitude tests are *not* biased (Hunt & Carlson, 2007; Neisser et al., 1996; Wigdor & Garner, 1982). The tests’ predictive validity is roughly the same for women and men, for Blacks and Whites, and for rich and poor. If an intelligence test score of 95 predicts slightly below-average grades, that rough prediction usually applies equally to all.

“Political equality is a commitment to universal human rights, and to policies that treat people as individuals rather than representatives of groups; it is not an empirical claim that all groups are indistinguishable.” -STEVEN PINKER (2006)

stereotype threat a self-confirming concern that one will be evaluated based on a negative stereotype.

“Math class is tough!” -“TEEN TALK” TALKING BARBIE DOLL (INTRODUCED JULY 1992, RECALLED OCTOBER 1992)

Test-Takers’ Expectations

Throughout this text, we have seen that our expectations and attitudes can influence our perceptions and behaviors, and we find this effect in intelligence testing. When Steven Spencer and his colleagues (1997) gave a difficult math test to equally capable men and women, women did not do as well—except when they had been led to expect that women usually do as well as men on the test. Otherwise, the women apparently felt apprehensive, which affected their performance. With Claude Steele and Joshua Aronson, Spencer (2002) also observed this self-fulfilling **stereotype threat** with Black students. When reminded of their race just before taking verbal aptitude tests, they performed worse. Follow-up experiments confirm that negatively stereotyped minorities and women may have unrealized academic potential (Nguyen & Ryan, 2008; Walton & Spencer, 2009). If, when taking an exam, you are worried that your type often doesn’t do well, your self-doubts and self-monitoring may hijack your working memory and impair your performance (Schmader, 2010). For such reasons, stereotype threat may also impair attention and learning (Inzlicht & Kang, 2010; Rydell et al., 2010).

Critics note that stereotype threat does not fully account for the Black-White aptitude score difference (Sackett et al., 2004, 2008). But it does help explain why Blacks have scored higher when tested by Blacks than when tested by Whites (Danso & Esses, 2001; Inzlicht & Ben-Zeev, 2000). It gives us insight into why women have scored higher on math tests with no male test-takers present, and why women’s chess play drops sharply when they *think* they are playing a male opponent (Maass et al., 2008). And it explains “the Obama effect”—

the finding that African-American adults performed better if taking a verbal aptitude test administered immediately after watching Barack Obama's stereotype-defying nomination acceptance speech or just after his 2008 presidential victory (Marx et al., 2009).

Steele (1995, 2010) concludes that telling students they probably won't succeed (as is sometimes implied by remedial "minority support" programs) functions as a stereotype that can erode performance. Over time, such students may detach their self-esteem from academics and look for recognition elsewhere. Indeed, as African-American boys progress from eighth to twelfth grade, there is a growing disconnect between their grades and their self-esteem and they tend to underachieve (Osborne, 1997). One experiment randomly assigned some African-American seventh-graders to write for 15 minutes about their most important values (Cohen et al., 2006, 2009). That simple exercise in self-affirmation had the apparent effect of boosting their semester grade point average by 0.26 in a first experiment and 0.34 in a replication. Minority students in university programs that challenge them to believe in their potential, or to focus on the idea that intelligence is malleable and not fixed, have likewise produced markedly higher grades and had lower dropout rates (Wilson, 2006).

What, then, can we realistically conclude about aptitude tests and bias? The tests are indeed biased (appropriately so, some would say) in one sense—sensitivity to performance differences caused by cultural experience. But they are not biased in the scientific sense of failing to make valid statistical predictions for different groups.

Bottom line: Are the tests discriminatory? Again, the answer can be *Yes* or *No*. In one sense, *Yes*, their purpose is to discriminate—to distinguish among individuals. In another sense, *No*, their purpose is to reduce discrimination by reducing reliance on subjective criteria for school and job placement—who you know, what school you're from, or whether you are the "right kind of person." Civil service aptitude tests, for example, were devised to discriminate more fairly and objectively by reducing the political, racial, and ethnic discrimination that preceded their use. Banning aptitude tests would lead those who decide on jobs and admissions to rely more on other considerations, such as personal opinion.

Perhaps, then, our goals for tests of mental abilities should be threefold. First, we should realize the benefits Alfred Binet foresaw—to enable schools to recognize who might profit most from early intervention. Second, we must remain alert to Binet's fear that intelligence test scores may be misinterpreted as literal measures of a person's worth and potential. Third, we must remember that the competence that general intelligence tests sample is important; it helps enable success in some life paths. But it reflects only one aspect of personal competence. Our practical intelligence and emotional intelligence matter, too, as do other forms of creativity, talent, and character. Because there are many ways of being successful, our differences are variations of human adaptability.

Finally, life's great achievements result not only from "can do" abilities but also from "will do" motivation. Competence + Diligence → Accomplishment.

Untestable compassion

Intelligence test scores are only one part of the picture of a whole person. They don't measure the abilities, talent, and commitment of, for example, people who devote their lives to helping others.

"Almost all the joyful things of life are outside the measure of IQ tests." -MADELEINE L'ENGLE, *A CIRCLE OF QUIET*, 1972

"[Einstein] showed that genius equals brains plus tenacity squared." -WALTER ISAACSON, *EINSTEIN'S FINAL QUEST*, 2009

Before You Move On

▶ ASK YOURSELF

How have your expectations influenced your own test performance? What steps could you take to control this influence?

▶ TEST YOURSELF

What is the difference between a test that is biased culturally, and a test that is biased in terms of its validity?

Answers to the Test Yourself questions can be found in Appendix E at the end of the book.

Module 64 Review

64-1 How and why do the genders differ in mental ability scores?

- Males and females tend to have the same average intelligence test scores. They differ in some specific abilities.
- Girls are better spellers, more verbally fluent, better at locating objects, better at detecting emotions, and more sensitive to touch, taste, and color.
- Boys outperform girls at spatial ability and related mathematics, though girls outperform boys in math computation. Boys also outnumber girls at the low and high extremes of mental abilities.
- Psychologists debate evolutionary, brain-based, and cultural explanations of such gender differences.

64-2 How and why do racial and ethnic groups differ in mental ability scores?

- Racial and ethnic groups differ in their average intelligence test scores.
- The evidence suggests that environmental differences are largely, perhaps entirely, responsible for these group differences.

64-3 Are intelligence tests inappropriately biased?

- Aptitude tests aim to predict how well a test-taker will perform in a given situation. So they are necessarily “biased” in the sense that they are sensitive to performance differences caused by cultural experience.
- By “inappropriately biased,” psychologists mean that a test predicts less accurately for one group than for another. In this sense, most experts consider the major aptitude tests unbiased.
- *Stereotype threat*, a self-confirming concern that one will be evaluated based on a negative stereotype, affects performance on all kinds of tests.

Multiple-Choice Questions

- Which of the following is true of boys compared with girls?
 - Boys have a higher average intelligence score.
 - Boys are better spellers than girls.
 - Boys are better at detecting emotions.
 - Boys are more verbally fluent.
 - Boys are more likely to have extremely low intelligence scores.
- Which of the following provides the best evidence that race is more of a social construct than a biological category?
 - People of varying ancestry may categorize themselves in the same race.
 - The races arose in different continents.
 - Behavior traits (like running speed) are associated with race.
 - Skin cancer rates vary by race.
 - The incidence of high blood pressure varies by race.
- According to most experts, intelligence tests are not biased because
 - the average scores for various racial and ethnic groups do not differ by much.
 - the tests do a pretty good job of predicting what they are supposed to predict.
 - cultural background has little influence on test scores.
 - scores on the test are not very stable even when you don't consider race.
 - scores are increasing for almost all groups because of the Flynn effect.

Practice FRQs

1. Robert and Maya are having an argument about whether intelligence tests are biased. Robert thinks they are but Maya insists they are not. How can they both be right?
2. Explain three reasons why racial differences in intelligence might be caused by environmental factors.
(3 points)

Answer

1 point: Intelligence tests can be considered biased because they, in part, measure experience. Therefore, people from a middle-class, or higher, background are at an advantage.

1 point: Intelligence tests do a good job of predicting the future no matter what demographic group the test-taker is from. In other words, children who do well on intelligence tests are likely to do well in school no matter what their economic or ethnic background is. Likewise, children from all backgrounds who do poorly on the tests do poorly in school.

Unit XI Review

Key Terms and Concepts to Remember

intelligence, p. 607	intelligence quotient (IQ), p. 618	content validity, p. 622
intelligence test, p. 607	achievement test, p. 619	predictive validity, p. 622
general intelligence (g), p. 608	aptitude test, p. 619	cohort, p. 625
factor analysis, p. 608	Wechsler Adult Intelligence Scale (WAIS), p. 620	crystallized intelligence, p. 626
savant syndrome, p. 609	standardization, p. 621	fluid intelligence, p. 626
grit, p. 610	normal curve, p. 621	intellectual disability, p. 629
emotional intelligence, p. 612	reliability, p. 622	Down syndrome, p. 629
mental age, p. 618	validity, p. 622	heritability, p. 632
Stanford-Binet, p. 618		stereotype threat, p. 642

Key Contributors to Remember

Charles Spearman, p. 608	Robert Sternberg, p. 611	Louis Terman, p. 618
L. L. Thurstone, p. 608	Francis Galton, p. 617	David Wechsler, p. 620
Howard Gardner, p. 609	Alfred Binet, p. 618	Carol Dweck, p. 635

AP[®] Exam Practice Questions

Multiple-Choice Questions

- Children are said to have an intellectual disability if they have difficulty adapting to the demands of independent living and have IQ scores below
 - 60.
 - 70.
 - 80.
 - 90.
 - 100.
- Charles Spearman's *g* refers to
 - general intelligence.
 - grouped intelligence factors.
 - genetic intelligence.
 - generated creativity.
 - generalized reliability.
- What would be true of a thermometer that always reads three degrees off?
 - It is valid but not reliable.
 - It is both reliable and valid.
 - It is neither reliable nor valid.
 - It is not valid, but you cannot determine if it is reliable from the information given.
 - It is reliable but not valid.
- In general, males score higher than females on tests of
 - spelling.
 - verbal fluency.
 - emotion detection.
 - spatial ability.
 - sensitivity to touch, taste, and odor.
- Achievement tests are to aptitude tests as
 - verbal performance is to spatial performance.
 - elementary school skills are to secondary school skills.
 - measurement is to prediction.
 - reliability is to validity.
 - general intelligence is to multiple intelligences.
- Howard Gardner found evidence of multiple intelligences in individuals who scored low on intelligence but had an area of exceptional ability—for example, to make complex calculations. These people have
 - the Flynn effect.
 - savant syndrome.
 - advanced mental age.
 - Wechsler syndrome.
 - intelligence heritability.
- Which of the following is one of Robert Sternberg's types of intelligence?
 - Naturalistic intelligence
 - General intelligence
 - Practical intelligence
 - Savant intelligence
 - Kinesthetic intelligence
- The Flynn effect refers to the
 - superiority of certain racial and ethnic groups on intelligence tests.
 - extreme scores (very high and very low scores) that are more common for males than females on math tests.
 - stereotype threat that might cause some Black students to underperform on standardized tests.
 - predictive ability of intelligence tests.
 - gradual improvement in intelligence test scores over the last several decades.
- The ability to perceive, understand, manage, and use emotions is called
 - interpersonal intelligence.
 - general intelligence.
 - practical intelligence.
 - emotional intelligence.
 - adaptive intelligence.
- Heritability of intelligence refers to
 - the extent to which a person's intelligence is caused by genetics.
 - the effect of adoption on the intelligence of adopted children.
 - the amount of group variation in intelligence that can be attributed to genetics.
 - the extent to which the quality of schools and other environmental factors determine intelligence.
 - the correlation between intelligence test scores of identical twins.
- Recent research about brain size and function suggests that
 - the occipital lobe is more active when people are thinking about questions on intelligence tests.
 - people who are smarter use less energy when solving problems.
 - there is no correlation between processing speed and IQ scores.
 - people with larger brains are always smarter than those with smaller brains.
 - subjects with larger parietal lobes tended to process information more slowly.

- 12.** The most widely used modern intelligence test was developed by
- Alfred Binet.
 - Louis Terman.
 - Robert Sternberg.
 - David Wechsler.
 - Howard Gardner.
- 13.** Students who do well on college entrance exams generally do well in their first year of college. This helps establish that these exams have
- predictive validity.
 - split-half reliability.
 - content validity.
 - test-retest reliability.
 - standard validity.
- 14.** The purpose of Alfred Binet's early intelligence test was to
- predict how children would do in school.
 - identify differences among ethnic and racial groups.
 - help French graduates find the occupation in which they were most likely to succeed.
 - establish the scientific definition of intelligence.
 - facilitate "genetic breeding" experiments.
- 15.** The original formula for a child's intelligence quotient compared a child's
- aptitude to his or her school performance.
 - mental age to his or her chronological age.
 - intelligence to his or her siblings' intelligence.
 - intelligence to his or her parents' intelligence.
 - math intelligence to his or her verbal intelligence.

Free-Response Questions

- 1.** Shervin is a high school student who excels in academics and usually scores very high on academic standardized tests. His friend, Hany, struggles in his coursework and with standardized tests, but is a brilliant pianist and dancer.

For each of the following intelligence theorists, briefly explain the psychologist's intelligence theory and identify how the theory might describe Shervin's and Hany's intelligence.

- Howard Gardner
- Robert Sternberg
- Charles Spearman

Rubric for Free Response Question

1 point: Gardner believed that there are eight intelligences: linguistic, musical, logical-mathematical, spatial, bodily-kinesthetic, intrapersonal, interpersonal, and naturalist. Individuals with the condition of savant syndrome exemplify his theory because they may score low on traditional intelligence tests, but have an extraordinary skill such as musical ability.  Pages 609–611

1 point: Gardner might describe Shervin as having high logical-mathematical and linguistic intelligence, and Hany as having high musical and bodily-kinesthetic intelligence.  Page 610

1 point: Sternberg's triarchic intelligence theory describes intelligence as a combination of three independent factors: creative, academic, and practical intelligence.  Page 611

1 point: Sternberg might predict that Shervin would score high in academic intelligence and Hany might score high in creative intelligence.  Page 611

1 point: According to Spearman's general intelligence theory, each individual has a general, underlying mental ability that can be measured. Spearman defined (and measured) intelligence as this general ability, which expresses itself on different mental tasks. For example, if an individual is above average academically in English, then he will most likely be at least average, if not above average academically in other subjects as well (such as math).  Pages 608–609

1 point: Spearman might predict that Shervin would score high on his test of general intelligence, but Hany would not since creativity in music and dance is not included as an aspect or expression of intelligence.  Page 608

- 2.** The principal of a new elementary school wants to give an IQ test to all students when they enter the school. The students will then be placed in groups of students of similar IQ scores. The principal assures the community that this plan is supported by scientific research and will improve education for all students, regardless of their ability.
- Using evidence, present an argument for or against intelligence testing for children early in life.
 - Using evidence, present an argument for or against schools that "track" children based on intelligence test scores, separating high scorers from students with lower scores.
 - Using evidence, present an argument supporting the claim that environmental influences affect intelligence.
 - Using evidence, present an argument supporting the claim that labeling or tracking students could lead to stereotype threat.

(4 points)

3. Professor Emic wants to first develop an intelligence test that can be used cross-culturally, and then to assess the reliability and validity of that test.

Briefly explain how Professor Emic could examine the following characteristics about this new intelligence test:

- Standardization
- Reliability
- Validity
- Bias

(4 points)

Unit XII

Abnormal Behavior

Modules

- 65** Introduction to Psychological Disorders
- 66** Anxiety Disorders, Obsessive-Compulsive Disorder, and Posttraumatic Stress Disorder
- 67** Mood Disorders
- 68** Schizophrenia
- 69** Other Disorders

I felt the need to clean my room at home in Indianapolis every Sunday and would spend four to five hours at it. I would take every book out of the bookcase, dust and put it back. . . . I couldn't stop.

Marc, diagnosed with obsessive-compulsive disorder (from Summers, 1996)

Whenever I get depressed it's because I've lost a sense of self. I can't find reasons to like myself. I think I'm ugly. I think no one likes me.

Greta, diagnosed with depression (from Thorne, 1993, p. 21)

Voices, like the roar of a crowd, came. I felt like Jesus; I was being crucified.

Stuart, diagnosed with schizophrenia (from Emmons et al., 1997)

People are fascinated by the exceptional, the unusual, the abnormal. "The sun shines and warms and lights us and we have no curiosity to know why this is so," observed Ralph Waldo Emerson, "but we ask the reason of all evil, of pain, and hunger, and [unusual] people."

Why such fascination with disturbed people? Even when we are well, do we see in them something of ourselves? At various moments, all of us feel, think, or act the way disturbed people do much of the time. We, too, get anxious, depressed, withdrawn, suspicious, or deluded, just less intensely and more briefly. No wonder studying psychological disorders sometimes evokes an eerie sense of self-recognition, one that illuminates our own personality. "To study the abnormal is the best way of understanding the normal," proposed William James (1842–1910).

Another reason for our curiosity is that so many of us have felt, either personally or through friends or family, the bewilderment and pain of a psychological disorder that may bring unexplained physical symptoms, irrational fears, or a feeling that life is not worth living. Indeed, as members of the human family, most of us will at some point encounter a person with a psychological disorder.

The World Health Organization (WHO, 2010) reports that, worldwide, some 450 million people suffer from mental or behavioral disorders. These disorders account for 15.4 percent of the years of life lost due to death or disability—scoring slightly below cardiovascular conditions and slightly above cancer (Murray & Lopez, 1996). Rates and symptoms of psychological disorders vary by culture, but two terrible maladies appear more consistently worldwide: depression and schizophrenia.

Module 65

Introduction to Psychological Disorders

Module Learning Objectives

- 65-1** Discuss how we draw the line between normality and disorder.
- 65-2** Discuss the controversy over the diagnosis of attention-deficit/hyperactivity disorder.
- 65-3** Contrast the medical model with the biopsychosocial approach to psychological disorders.
- 65-4** Describe how and why clinicians classify psychological disorders.
- 65-5** Explain why some psychologists criticize the use of diagnostic labels.
- 65-6** Discuss the prevalence of psychological disorders, and summarize the findings on the link between poverty and serious psychological disorders.

chinaface/Getty Images

Most people would agree that someone who is too depressed to get out of bed for weeks at a time has a psychological disorder. But what about those who, having experienced a loss, are unable to resume their usual social activities? Where should we draw the line between sadness and depression? Between zany creativity and bizarre irrationality? Between normality and abnormality? Let's start with these questions:

- How should we *define* psychological disorders?
- How should we *understand* disorders? How do underlying biological factors contribute to disorder? How do troubling environments influence our well-being? And how do these effects of nature and nurture interact?
- How should we *classify* psychological disorders? And can we do so in a way that allows us to help people without stigmatizing them with *labels*?

“Who in the rainbow can draw the line where the violet tint ends and the orange tint begins? Distinctly we see the difference of the colors, but where exactly does the one first blendingly enter into the other? So with sanity and insanity.” -HERMAN MELVILLE, *BILLY BUDD, SAILOR*, 1924

Defining Psychological Disorders

65-1 How should we draw the line between normality and disorder?

A **psychological disorder** is a syndrome marked by a “clinically significant disturbance in an individual’s cognition, emotion regulation, or behavior” (American Psychiatric Association, 2013). Disturbed, or *dysfunctional*, behaviors are *maladaptive*—they interfere with normal day-to-day life. An intense fear of spiders may be abnormal, but if it doesn’t interfere with your life, it is not a disorder. Marc’s cleaning rituals (from this unit’s opening) did interfere with his work and leisure. If occasional sad moods persist and become disabling, they may signal a psychological disorder. Distress often accompanies dysfunctional behaviors. Marc, Greta, and Stuart were all distressed by their behaviors or emotions.

Over time, definitions of what makes for a “significant disturbance” have varied. From 1952 through December 9, 1973, homosexuality was classified as a mental illness. By day’s end on December 10, it was not. The American Psychiatric Association had dropped homosexuality as a disorder because more and more of its members no longer viewed it as a psychological problem. (Later research revealed that the stigma and stresses that often accompany homosexuality, however, increase the risk of mental health problems [Hatzenbuehler et al., 2009; Meyer, 2003].) In this new century, controversy swirls over the frequent diagnosing of children with *attention-deficit/hyperactivity disorder* (see Thinking Critically About: ADHD—Normal High Energy or Disordered Behavior? on the next page).

psychological disorder

a syndrome marked by a clinically significant disturbance in an individual’s cognition, emotion regulation, or behavior. (Adapted from American Psychiatric Association, 2013.)

iStock/Thinkstock

Culture and normality

Young men of the West African Wodaabe tribe put on elaborate makeup and costumes to attract women. Young American men may buy flashy cars with loud stereos to do the same. Each culture may view the other’s behavior as abnormal.

Understanding Psychological Disorders

65-3 How do the medical model and the biopsychosocial approach understand psychological disorders?

To explain puzzling behavior, people in earlier times often presumed the work of strange forces—the movements of the stars, godlike powers, or evil spirits. Had you lived during the Middle Ages, you might have said, “The devil made him do it,” and you might have

Yesterday’s “therapy” In other times and places, psychologically disordered people sometimes received brutal treatments, including the trephination evident in this Stone Age skull. Drilling skull holes like these may have been an attempt to release evil spirits and cure those with mental disorders. Did this patient survive the “cure”?

John W. Verano

approved of a cure to rid the evil force by exorcising the demon. Until the last two centuries, “mad” people were sometimes caged in zoo-like conditions or given “therapies” appropriate to a demon: beatings, burning, or castration. In other times, therapy included pulling teeth, removing lengths of intestines, cauterizing the clitoris, or giving transfusions of animal blood (Farina, 1982).

Thinking Critically About

ADHD—Normal High Energy or Disordered Behavior?

65-2

Why is there controversy over attention-deficit/hyperactivity disorder?

Eight-year-old Todd has always been energetic. At home, he chatters away and darts from one activity to the next, rarely settling down to read a book or focus on a game. At play, he is reckless and overreacts when playmates bump into him or take one of his toys. At school, his exasperated teacher complains that fidgety Todd doesn't listen, follow instructions, or stay in his seat and do his lessons. As he matures to adulthood, Todd's hyperactivity likely will subside, but his inattentiveness may persist (Kessler et al., 2010).

If taken for a psychological evaluation, Todd may be diagnosed with **attention-deficit/hyperactivity disorder (ADHD)**, as are some 11 percent of American 4- to 17-year-olds who display its key symptoms (extreme inattention, hyperactivity, and impulsivity) (Schwarz & Cohen, 2013). Studies also find 2.5 percent of adults—though a diminishing number with age—exhibiting ADHD symptoms (Simon et al., 2009). Psychiatry's new diagnostic manual loosens the criteria for adult ADHD, leading critics to fear increased diagnosis and overuse of prescription drugs (Frances, 2012).

To skeptics, being distractible, fidgety, and impulsive sounds like a “disorder” caused by a single genetic variation: a Y chromosome. And sure enough, ADHD is diagnosed three times more often in boys than in girls. Does energetic child + boring school = ADHD overdiagnosis? Is the label being applied to healthy schoolchildren who, in more natural outdoor environments, would seem perfectly normal?

Skeptics think so. In the decade after 1987, they note, the proportion of American children being treated for ADHD nearly quadrupled (Olson et al., 2003). How commonplace the diagnosis is depends in part on teacher referrals. Some teachers refer lots of kids for ADHD assessment, others none. ADHD rates have varied by a factor of 10 in different counties of New York State (Carlson, 2000). Although African-American youth display more ADHD symptoms than do Caucasian youth, they less often receive an ADHD diagnosis (Miller et al., 2009). Depending on where they live, children who are “a persistent pain in the neck in school” are often diagnosed with ADHD and given powerful prescription drugs, notes Peter Gray (2010). But the problem resides less in the child, he argues, than in today's abnormal environment

that forces children to do what evolution has not prepared them to do—to sit for long hours in chairs.

On the other side of the debate are those who argue that the more frequent diagnoses of ADHD today reflect increased awareness of the disorder, especially in those areas where rates are highest. They acknowledge that diagnoses can be subjective and sometimes inconsistent—ADHD is not as objectively defined as is a broken arm. Nevertheless, declared the World Federation for Mental Health (2005), “there is strong agreement among the international scientific community that ADHD is a real neurobiological disorder whose existence should no longer be debated.” A consensus statement by 75 researchers noted that in neuroimaging studies, ADHD has associations with abnormal brain activity patterns (Barkley et al., 2002).

What, then, is known about ADHD's causes? It is not caused by too much sugar or poor schools. There is mixed evidence suggesting that extensive TV watching and video gaming are associated with reduced cognitive self-regulation and ADHD (Bailey et al., 2011; Courage & Setliff, 2010; Ferguson, 2011). ADHD often coexists with a learning disorder or with defiant and temper-prone behavior. ADHD is *heritable*, and research teams are sleuthing the culprit genes and abnormal neural pathways (Nikolas & Burt, 2010; Poelmans et al., 2011; Volkow et al., 2009; Williams et al., 2010). It is treatable with medications such as Ritalin and Adderall, which are considered stimulants but help calm hyperactivity and increase the ability to sit and focus on a task—and to progress normally in school (Barbaresi et al., 2007). Psychological therapies, such as those focused on shaping behaviors in the classroom and at home, have also helped address the distress of ADHD (Fabiano et al., 2008).

The bottom line: Extreme inattention, hyperactivity, and impulsivity can derail social, academic, and vocational achievements, and these symptoms can be treated with medication and other therapies. But the debate continues over whether normal rambunctiousness is too often diagnosed as a psychiatric disorder, and whether there is a cost to the long-term use of stimulant drugs in treating ADHD.

attention-deficit/hyperactivity disorder (ADHD)

a psychological disorder marked by the appearance by age 7 of one or more of three key symptoms: extreme inattention, hyperactivity, and impulsivity.

The Medical Model

In opposition to brutal treatments, reformers, including Philippe Pinel (1745–1826) in France, insisted that madness is not demon possession but a sickness of the mind caused by severe stresses and inhumane conditions. For Pinel and others, “moral treatment” included boosting patients’ morale by unchaining them and talking with them, and by replacing brutality with gentleness, isolation with activity, and filth with clean air and sunshine. While such measures did not often cure patients, they were certainly more humane.

By the 1800s, the discovery that syphilis infects the brain and distorts the mind drove further gradual reform. Hospitals replaced asylums, and the medical world began searching for physical causes and treatments of mental disorders. Today, this **medical model** is recognizable in the terminology of the mental *health* movement: A mental *illness* (also called a *psychopathology*) needs to be *diagnosed* on the basis of its *symptoms* and *treated* through *therapy*, which may include time in a psychiatric *hospital*.

The medical perspective has gained credibility from recent discoveries that genetically influenced abnormalities in brain structure and biochemistry contribute to many disorders. But as we will see, psychological factors, such as chronic or traumatic stress, also play an important role.

medical model the concept that diseases, in this case psychological disorders, have physical causes that can be *diagnosed*, *treated*, and, in most cases, *cured*, often through treatment in a *hospital*.

Dance in a Madhouse, 1917 (litho), Bellows, George Wesley (1862–1925)/San Diego Museum of Art, USA/Museum Purchase/The Bridgeman Art Library

“Moral treatment” Under Philippe Pinel’s influence, hospitals sometimes sponsored patient dances, often called “lunatic balls,” depicted in this painting by George Bellows (*Dance in a Madhouse*).

The Biopsychosocial Approach

Today’s psychologists contend that all behavior, whether called normal or disordered, arises from the interaction of nature (genetic and physiological factors) and nurture (past and present experiences). To presume that a person is “mentally ill,” they say, attributes the condition to a “sickness” that must be identified and cured. But difficulty in the person’s environment, the person’s current interpretations of events, or the person’s bad habits and poor social skills may also be factors.

Evidence of such effects comes from links between specific disorders and cultures (Beardsley, 1994; Castillo, 1997). Cultures differ in their sources of stress, and they produce different ways of coping. The eating disorders anorexia nervosa and bulimia nervosa, for example, have occurred mostly in Western cultures. In Malaysia, *amok* describes a sudden outburst of violent behavior (thus the phrase “run amok”). Latin America lays claim to *susto*, a condition marked by severe anxiety, restlessness, and a fear of black magic. *Taijin-kyofusho*, social anxiety about one’s appearance combined with a readiness to blush and a fear of eye contact, appears in Japan, as does the extreme withdrawal of *hikikomori*. Such disorders may share an underlying dynamic (such as anxiety) while differing in the symptoms (an eating problem or a type of fear) manifested in a particular culture.

But not all disorders are culture-bound. Depression and schizophrenia occur worldwide. From Asia to Africa and across the Americas, schizophrenia’s symptoms often include irrationality and incoherent speech.

FYI

Increasingly, North American disorders, such as eating disorders, are, along with McDonald’s and MTV, spreading across the globe (Watters, 2010).

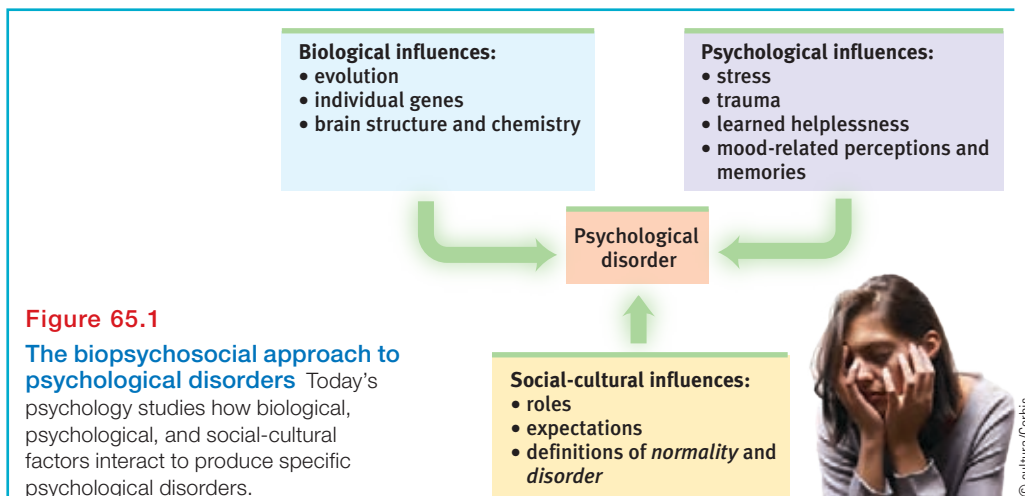

Figure 65.1

The biopsychosocial approach to psychological disorders

Today's psychology studies how biological, psychological, and social-cultural factors interact to produce specific psychological disorders.

To assess the whole set of influences—genetic predispositions and physiological states, inner psychological dynamics, and social and cultural circumstances—the biopsychosocial model helps (FIGURE 65.1). This approach recognizes that mind and body are inseparable. Negative emotions contribute to physical illness, and physical abnormalities contribute to negative emotions. We are mind embodied and socially embedded.

Classifying Psychological Disorders

65-4 How and why do clinicians classify psychological disorders?

In biology and the other sciences, classification creates order. To classify an animal as a “mammal” says a great deal—that it is warm-blooded, has hair or fur, and nourishes its young with milk. In psychiatry and psychology, too, classification orders and describes symptoms. To classify a person’s disorder as “schizophrenia” suggests that the person talks incoherently; hallucinates or has delusions (bizarre beliefs); shows either little emotion or inappropriate emotion; or is socially withdrawn. “Schizophrenia” provides a handy shorthand for describing a complex disorder.

In psychiatry and psychology, diagnostic classification aims not only to describe a disorder but also to predict its future course, imply appropriate treatment, and stimulate research into its causes. Indeed, to study a disorder we must first name and describe it. The most common system for describing disorders and estimating how often they occur is the American Psychiatric Association’s 2013 *Diagnostic and Statistical Manual of Mental Disorders*, now in its fifth edition (**DSM-5**). Physicians and mental health workers use the detailed “diagnostic criteria and codes” in the DSM-5 to guide medical diagnoses and define who is eligible for treatments, including medication. For example, a person may be diagnosed with and treated for “insomnia disorder” if he or she meets *all* of the following criteria:

- Is dissatisfied with sleep quantity or quality (difficulty initiating, maintaining, or returning to sleep).
- Sleep disturbance causes distress or impairment in everyday functioning.
- Occurs at least three nights per week.
- Present for at least three months.
- Occurs despite adequate opportunity for sleep.
- Is not explained by another sleep disorder (such as narcolepsy).
- Is not caused by substance use or abuse.
- Is not caused by other mental disorders or medical conditions.

In this new DSM edition, some diagnostic labels have changed. For example, “autism” and “Asperger’s syndrome” are no longer included; they have been combined into “autism spectrum disorder.” “Mental retardation” has become “intellectual disability.” New categories include “hoarding disorder” and “binge-eating disorder.”

FYI

A book of case illustrations accompanying the previous DSM edition provides several examples for this unit.

DSM-5 the American Psychiatric Association’s *Diagnostic and Statistical Manual of Mental Disorders*, Fifth Edition; a widely used system for classifying psychological disorders.

Some new or altered diagnoses are controversial. “Disruptive mood dysregulation disorder” is a new DSM-5 diagnosis for children “who exhibit persistent irritability and frequent episodes of behavior outbursts three or more times a week for more than a year.” Will this diagnosis assist parents who struggle with unstable children, or will it “turn temper tantrums into a mental disorder” and lead to overmedication, as the chair of the previous DSM edition has warned (Frances, 2012)?

Critics have long faulted the DSM for casting too wide a net and bringing “almost any kind of behavior within the compass of psychiatry” (Eysenck et al., 1983). They worry that the DSM-5 will extend the pathologizing of everyday life—for example, by turning bereavement grief into depression and boyish rambunctiousness into ADHD (Frances, 2013). Others respond that depression and hyperactivity, though needing careful definition, are genuine disorders even, for example, those triggered by a major life stress such as a death when the grief does not go away (Kendler, 2011; Kupfer, 2012).

“I’m always like this, and my family was wondering if you could prescribe a mild depressant.”

Labeling Psychological Disorders

65-5 Why do some psychologists criticize the use of diagnostic labels?

The DSM has other critics who register a more fundamental complaint—that these labels are at best arbitrary and at worst value judgments masquerading as science. Once we label a person, we view that person differently (Farina, 1982). Labels create preconceptions that guide our perceptions and our interpretations.

In a now-classic study of the biasing power of labels, David Rosenhan (1973) and seven others went to hospital admissions offices, complaining of “hearing voices” saying *empty*, *hollow*, and *thud*. Apart from this complaint and giving false names and occupations, they answered questions truthfully. All eight normal people were misdiagnosed with disorders.

Should we be surprised? As one psychiatrist noted, if someone swallows blood, goes to an emergency room, and spits it up, should we fault the doctor for diagnosing a bleeding ulcer? Surely not. But what followed the diagnosis in the Rosenhan study was startling. Until being released an average of 19 days later, the “patients” exhibited no further symptoms such as hearing voices. Yet after analyzing their (quite normal) life histories, clinicians were able to “discover” the causes of their disorders, such as reacting with mixed emotions about a parent. Even the routine behavior of taking notes was misinterpreted as a symptom.

Labels matter. When people in another experiment watched videotaped interviews, those told the interviewees were job applicants perceived them as normal (Langer et al., 1974, 1980). Those who thought they were watching psychiatric or cancer patients perceived them as “different from most people.” Therapists who thought an interviewee was a psychiatric patient perceived him as “frightened of his own aggressive impulses,” a “passive, dependent type,” and so forth. A label can, as Rosenhan discovered, have “a life and an influence of its own.”

Surveys in Europe and North America have demonstrated the stigmatizing power of labels (Page, 1977). Getting a job or finding a place to rent can be a challenge for those known to be just released from prison—or a mental hospital. But as we are coming to understand that many psychological disorders are diseases of the brain, not failures of character, the stigma seems to be lifting (Solomon, 1996). Public figures are feeling freer to “come out” and speak with candor about their struggles with disorders such as depression. And the more contact people have with individuals with disorders, the more accepting their attitudes are (Kolodziej & Johnson, 1996). People express greatest sympathy for people whose disorders are gender atypical—for men suffering depression (which is more common among women), or for women plagued by alcohol use disorder (Wirth & Bodenhausen, 2009).

“One of the unpardonable sins, in the eyes of most people, is for a man to go about unlabeled. The world regards such a person as the police do an unmuzzled dog, not under proper control.” -T. H. HUXLEY, *EVOLUTION AND ETHICS*, 1893

“My sister suffers from a bipolar disorder and my nephew from schizoaffective disorder. There has, in fact, been a lot of depression and alcoholism in my family and, traditionally, no one ever spoke about it. It just wasn’t done. The stigma is toxic.” -ACTRESS GLENN CLOSE, “MENTAL ILLNESS: THE STIGMA OF SILENCE,” 2009

Accurate portrayal

Recent films have offered some realistic depictions of psychological disorders. *Black Swan* (2010), shown here, portrayed a main character suffering a delusional disorder. *Temple Grandin* (2010) dramatized a lead character who successfully copes with autism spectrum disorder. *A Single Man* (2009) depicted depression.

Protozoa Pictures/Phoenix Pictures/The Kobal Collection

AP® Exam Tip

Notice that the term *insanity* comes out of the legal system. It is not a psychological or medical diagnosis and does not appear in the DSM-5.

violence than the perpetrators (Marley & Bulia, 2001). Indeed, reported the U.S. Surgeon General's Office (1999, p. 7), "There is very little risk of violence or harm to a stranger from casual contact with an individual who has a mental disorder." (Although most people with psychological disorders are not violent, those who are create a moral dilemma for society. For more on this topic, see Thinking Critically About: Insanity and Responsibility.)

Thinking Critically About**Insanity and Responsibility**

"My brain . . . my genes . . . my bad upbringing made me do it." Such defenses were anticipated by Shakespeare's Hamlet. If I wrong someone when not myself, he explained, "then Hamlet does it not, Hamlet denies it. Who does it then? His madness." Such is the essence of a legal insanity defense. "Insanity" is a legal rather than a psychological concept, and was created in 1843 after a deluded Scotsman tried to shoot the prime minister (who he thought was persecuting him) but killed an assistant by mistake. Like U.S. President Ronald Reagan's near-assassin, John Hinckley, Scotsman Daniel M'Naghten was sent to a mental hospital rather than to prison.

In both cases, the public was outraged. "Hinckley Insane, Public Mad," declared one headline. They were mad again when a deranged Jeffrey Dahmer in 1991 admitted murdering 15 young men and eating parts of their bodies. They were mad in 1998 when 15-year-old Kip Kinkel, driven by "those voices in my head," killed his parents and two fellow Springfield, Oregon, students and wounded 25 others. They were mad in 2002 when Andrea Yates, after being taken off her antipsychotic medication, was tried in Texas for drowning her five children. And they were mad in 2011, when an irrational Jared Loughner gunned down a crowd of people, including survivor Congresswoman Gabrielle Giffords, in an Arizona supermarket parking lot. Following their arrest, most of these people were sent to jails, not hospitals. (Hinckley was sent to a psychiatric hospital and later, after another trial, Yates was instead hospitalized.) As Yates' fate illustrates, 99 percent of those whose insanity defense is accepted are nonetheless institutionalized, often for as long as those convicted of crimes (Lilienfeld & Arkowitz, 2011).

HANDOUT/Reuters/Corbis

Jail or hospital? Jared Lee Loughner was charged with the 2011 Tucson, Arizona, shooting that killed six people and left over a dozen others injured, including U.S. Representative Gabrielle Giffords. Loughner had a history of mental health issues, including paranoid beliefs, and was diagnosed with schizophrenia. Usually, however, schizophrenia is only associated with violence when accompanied by substance abuse (Fazel et al., 2009).

Most people with psychological disorders are not violent. But what should society do with those who are? What do we do with disturbed individuals who mow down innocents at movie theaters and schools? Sometimes there is nothing to be done, as in the case of the 2012 Sandy Hook Elementary School tragedy in Connecticut, where the shooter's final fatal shot was self-inflicted. Many people who have been executed or are now on death row have been limited by intellectual disability or motivated by delusional voices. The State of Arkansas forced one murderer with schizophrenia, Charles Singleton, to take two anti-psychotic drugs—in order to make him mentally competent, so that he could then be put to death.

Which of Yates' two juries made the right decision? The first, which decided that people who commit such rare but terrible crimes should be held responsible? Or the second, which decided to blame the "madness" that clouds their vision? As we come to better understand the biological and environmental basis for all human behavior, from generosity to vandalism, when should we—and should we not—hold people accountable for their actions?

Not only can labels bias perceptions, they can also change reality. When teachers are told certain students are “gifted,” when students expect someone to be “hostile,” or when interviewers check to see whether someone is “extraverted,” they may act in ways that elicit the very behavior expected (Snyder, 1984). Someone who was led to think you are nasty may treat you coldly, leading you to respond as a mean-spirited person would. Labels can serve as self-fulfilling prophecies.

But let us remember the *benefits* of diagnostic labels. Mental health professionals use labels to communicate about their cases, to comprehend the underlying causes, and to discern effective treatment programs. Diagnostic definitions also inform patient self-understandings. And they are useful in research that explores the causes and treatments of disordered behavior.

Rates of Psychological Disorders

65-6 How many people suffer, or have suffered, from a psychological disorder? Is poverty a risk factor?

Who is most vulnerable to psychological disorders? At what times of life? To answer such questions, various countries have conducted lengthy, structured interviews with representative samples of thousands of their citizens. After asking hundreds of questions that probed for symptoms—“Has there ever been a period of two weeks or more when you felt like you wanted to die?”—the researchers have estimated the current, prior-year, and lifetime prevalence of various disorders.

How many people have, or have had, a psychological disorder? More than most of us suppose:

- The U.S. National Institute of Mental Health (2008, based on Kessler et al., 2005) estimates that 26 percent of adult Americans “suffer from a diagnosable mental disorder in a given year” (**TABLE 65.1**).
- A large-scale World Health Organization (2004a) study—based on 90-minute interviews of 60,463 people—estimated the number of prior-year mental disorders in 20 countries. As **FIGURE 65.2** displays, the lowest rate of reported mental disorders was in Shanghai, the highest rate in the United States. Moreover, immigrants to the United States from Mexico, Africa, and Asia average better mental health than their native U.S. counterparts (Breslau et al., 2007; Maldonado-Molina et al., 2011). For example, compared with people who have recently immigrated from Mexico, Mexican-Americans born in the United States are at greater risk of mental disorder—a phenomenon known as the *immigrant paradox* (Schwartz et al., 2010).

Table 65.1 Percentage of Americans Reporting Selected Psychological Disorders in the Past Year

Psychological Disorder	Percentage
Generalized anxiety	3.1
Social anxiety disorder	6.8
Phobia of specific object or situation	8.7
Mood disorder	9.5
Obsessive-compulsive disorder (OCD)	1.0
Schizophrenia	1.1
Posttraumatic stress disorder (PTSD)	3.5
Attention-deficit/hyperactivity disorder (ADHD)	4.1
Any mental disorder	26.2

Source: National Institute of Mental Health, 2008.

Figure 65.2 Prior-year prevalence of disorders in selected areas From World Health Organization (WHO, 2004a) interviews in 20 countries.

Who is most vulnerable to mental disorders? As we have seen, the answer varies with the disorder. One predictor of mental disorder, poverty, crosses ethnic and gender lines. The incidence of serious psychological disorders has been doubly high among those below the poverty line (CDC, 1992). Like so many other correlations, the poverty-disorder association raises a chicken-and-egg question: Does poverty cause disorders? Or do disorders cause poverty? It is both, though the answer varies with the disorder. Schizophrenia understandably leads to poverty. Yet the stresses and demoralization of poverty can also precipitate disorders, especially depression in women and substance use disorder in men (Dohrenwend et al., 1992). In one natural experiment on the poverty-pathology link, researchers tracked rates of behavior problems in North Carolina Native American children as economic development enabled a dramatic reduction in their community's poverty rate. As the study began, children of poverty exhibited more deviant and aggressive behaviors. After four years, children whose families had moved above the poverty line exhibited a 40 percent decrease in the behavior problems, while those who continued in their previous positions below or above the poverty line exhibited no change (Costello et al., 2003).

As **TABLE 65.2** indicates, there is a wide range of risk and protective factors for mental disorders. At what times of life do disorders strike? Usually by early adulthood. "Over 75 percent of our sample with any disorder had experienced its first symptoms by age 24," reported Lee Robins and Darrel Regier (1991, p. 331). The symptoms of antisocial personality disorder and of phobias are among the earliest to appear, at a median age of 8 and 10, respectively. Symptoms of alcohol use disorder, obsessive-compulsive disorder, bipolar disorder, and schizophrenia appear at a median age near 20. Major depression often hits somewhat later, at a median age of 25. Such findings make clear the need for research and treatment to help the growing number of people, especially teenagers and young adults, who suffer the bewilderment and pain of a psychological disorder.

Table 65.2 Risk and Protective Factors for Mental Disorders

Risk Factors	Protective Factors
Academic failure	Aerobic exercise
Birth complications	Community offering empowerment, opportunity, and security
Caring for chronically ill or patients with neurocognitive disorder	Economic independence
Child abuse and neglect	Effective parenting
Chronic insomnia	Feelings of mastery and control
Chronic pain	Feelings of security
Family disorganization or conflict	Literacy
Low birth weight	Positive attachment and early bonding
Low socioeconomic status	Positive parent-child relationships
Medical illness	Problem-solving skills
Neurochemical imbalance	Resilient coping with stress and adversity
Parental mental illness	Self-esteem
Parental substance abuse	Social and work skills
Personal loss and bereavement	Social support from family and friends
Poor work skills and habits	
Reading disabilities	
Sensory disabilities	
Social incompetence	
Stressful life events	
Substance abuse	
Trauma experiences	

Source: World Health Organization (WHO, 2004b,c).

Although mindful of the pain, we can also be encouraged by the many successful people—including Leonardo da Vinci, Isaac Newton, and Leo Tolstoy—who pursued brilliant careers while enduring psychological difficulties. So have 18 U.S. presidents, including the periodically depressed Abraham Lincoln, according to one psychiatric analysis of their biographies (Davidson et al., 2006). The bewilderment, fear, and sorrow caused by psychological disorders are real. But, as Unit XIII shows, hope, too, is real.

Before You Move On

▶ ASK YOURSELF

How would you draw the line between sending disturbed criminals to prisons or to mental hospitals? Would the person's history (for example, having suffered child abuse) influence your decisions?

▶ TEST YOURSELF

What is the biopsychosocial approach, and why is it important in our understanding of psychological disorders?

Answers to the Test Yourself questions can be found in Appendix E at the end of the book.

Module 65 Review

65-1

How should we draw the line between normality and disorder?

- According to psychologists and psychiatrists, a *psychological disorder* is a syndrome marked by a clinically significant disturbance in an individual's cognition, emotion regulation, or behavior.

65-2

Why is there some controversy over attention-deficit/hyperactivity disorder?

- A child who by age 7 displays extreme inattention, hyperactivity, and impulsivity may be diagnosed with *attention-deficit/hyperactivity disorder (ADHD)* and treated with medication and other therapy.
- The controversy centers on whether the growing number of ADHD cases reflects overdiagnosis or increased awareness of the disorder. Long-term effects of stimulant-drug treatment for ADHD are not yet known.

65-3

How do the medical model and the biopsychosocial approach understand psychological disorders?

- The *medical model* assumes that psychological disorders are mental illnesses with physical causes that can be diagnosed, treated, and, in most cases, cured through therapy, sometimes in a hospital.

- The biopsychosocial approach assumes that three sets of influences—biological (evolution, genetics, brain structure and chemistry), psychological (stress, trauma, learned helplessness, mood-related perceptions and memories), and social-cultural (roles, expectations, definitions of “normality” and “disorder”)—interact to produce specific psychological disorders.

65-4

How and why do clinicians classify psychological disorders?

- The American Psychiatric Association's *DSM-5 (Diagnostic and Statistical Manual of Mental Disorders, Fifth Edition)* contains diagnostic labels and descriptions that provide a common language and shared concepts for communication and research.
- Some critics believe the DSM editions have become too detailed and extensive.

65-5

Why do some psychologists criticize the use of diagnostic labels?

- Other critics view DSM diagnoses as arbitrary labels that create preconceptions which bias perceptions of the labeled person's past and present behavior. The legal label, "insanity," raises moral and ethical questions about whether society should hold people with disorders responsible for their violent actions.
- Most people with disorders are nonviolent and are more likely to be victims than attackers.

65-6

How many people suffer, or have suffered, from a psychological disorder? Is poverty a risk factor?

- Psychological disorder rates vary, depending on the time and place of the survey. In one multinational survey, rates for any disorder ranged from less than 5 percent (Shanghai) to more than 25 percent (the United States).
- Poverty is a risk factor: Conditions and experiences associated with poverty contribute to the development of psychological disorders. But some disorders, such as schizophrenia, can drive people into poverty.

Multiple-Choice Questions

- Which of the following describes the idea that psychological disorders can be diagnosed and treated?
 - Taijin-kyofusho
 - The DSM
 - The biopsychosocial approach
 - Amok
 - The medical model
- Which of the following is the primary purpose of the DSM?
 - Diagnosis of mental disorders
 - Selection of appropriate psychological therapies for mental disorders
 - Placement of mental disorders in appropriate cultural context
 - Selection of appropriate medicines to treat mental disorders
 - Understanding the causes of mental disorders
- Which of the following disorders do Americans report most frequently?
 - Schizophrenia
 - Mood disorders
 - Posttraumatic stress disorder (PTSD)
 - Obsessive-compulsive disorder (OCD)
 - Attention-deficit/hyperactivity disorder (ADHD)

Practice FRQs

- Name and describe the two major approaches to understanding psychological disorders.
- Explain two criticisms of the DSM. (2 points)

Answer

2 points: The medical model, which is an attempt to first diagnose and then treat psychological disorders.

2 points: The biopsychosocial approach, which is an attempt to understand psychological disorders as an interaction of biological, psychological, and social-cultural factors.

Module 66

Anxiety Disorders, Obsessive-Compulsive Disorder, and Posttraumatic Stress Disorder

Module Learning Objectives

- 66-1** Identify the different anxiety disorders.
- 66-2** Describe obsessive-compulsive disorder.
- 66-3** Describe posttraumatic stress disorder.
- 66-4** Describe how the learning and biological perspectives explain anxiety disorders, OCD, and PTSD.

Andrew Bengel/Redskins via Getty Images

66-1 What are the different anxiety disorders?

Anxiety is part of life. Speaking in front of a class, peering down from a ladder, or waiting to play in a big game, any one of us might feel anxious (even seasoned performers like Green Day's Billie Joe Armstrong, whose anxiety and substance abuse resulted in cancelled concerts in 2012 and 2013). At times we may feel enough anxiety to avoid making eye contact or talking with someone—"shyness," we call it. Fortunately for most of us, our uneasiness is not intense and persistent.

Some of us, however, are more prone to notice and remember threats (Mitte, 2008). This tendency may place us at risk for one of the **anxiety disorders**, marked by distressing, persistent anxiety or dysfunctional anxiety-reducing behaviors. We will consider these three:

- *Generalized anxiety disorder*, in which a person is unexplainably and continually tense and uneasy
- *Panic disorder*, in which a person experiences sudden episodes of intense dread
- *Phobias*, in which a person is intensely and irrationally afraid of a specific object or situation

Two other disorders involve anxiety, though the DSM-5 now classifies them separately:

- *Obsessive-compulsive disorder*, in which a person is troubled by repetitive thoughts or actions
- *Posttraumatic stress disorder*, in which a person has lingering memories, nightmares, and other symptoms for weeks after a severely threatening, uncontrollable event

anxiety disorders psychological disorders characterized by distressing, persistent anxiety or maladaptive behaviors that reduce anxiety.

Snapshots

Obsessing about obsessive-compulsive disorder

AP® Exam Tip

The way disorders are classified can be confusing, so it's worth taking some time to keep the organization straight. Sometimes, there is a broad classification that includes more specific disorders—the broad category of anxiety disorders, for example, includes generalized anxiety disorder, panic disorder, and phobia. Other times, there is just one level of classification. Obsessive-compulsive disorder and posttraumatic stress disorder do not fit into broader categories.

Generalized Anxiety Disorder

For the past two years, Tom, a 27-year-old electrician, has been bothered by dizziness, sweating palms, heart palpitations, and ringing in his ears. He feels edgy and sometimes finds himself shaking. With reasonable success, he hides his symptoms from his family and co-workers. But he allows himself few other social contacts, and occasionally he has to leave work. His family doctor and a neurologist can find no physical problem.

Tom's unfocused, out-of-control, agitated feelings suggest a **generalized anxiety disorder**, which is marked by pathological worry. The symptoms of this disorder are commonplace; their persistence, for six months or more, is not. People with this condition—two-thirds are women (McLean & Anderson, 2009)—worry continually, and they are often jittery, agitated, and sleep-deprived. Concentration is difficult as attention switches from worry to worry, and their tension and apprehension may leak out through furrowed brows, twitching eyelids, trembling, perspiration, or fidgeting.

One of generalized anxiety disorder's worst characteristics is that the person may not be able to identify, and therefore deal with or avoid, its cause. To use Sigmund Freud's term, the anxiety is *free-floating*. Generalized anxiety disorder is often accompanied by depressed mood, but even without depression it tends to be disabling (Hunt et al., 2004; Moffitt et al., 2007b). Moreover, it may lead to physical problems, such as high blood pressure.

Many people with generalized anxiety disorder were maltreated and inhibited as children (Moffitt et al., 2007a). As time passes, however, emotions tend to mellow, and by age 50, generalized anxiety disorder becomes fairly rare (Rubio & López-Ibor, 2007).

Panic Disorder

Panic disorder entails an anxiety tornado. Panic strikes suddenly, wreaks havoc, and disappears. For the 1 person in 75 with this disorder, anxiety suddenly escalates into a terrifying *panic attack*—a minutes-long episode of intense fear that something horrible is about to happen. Heart palpitations, shortness of breath, choking sensations, trembling, or dizziness typically accompany the panic, which may be misperceived as a heart attack or other serious physical ailment. Smokers have at least a doubled risk of panic disorder (Zvolensky & Bernstein, 2005). Because nicotine is a stimulant, lighting up doesn't lighten up.

One woman recalled suddenly feeling “hot and as though I couldn't breathe. My heart was racing and I started to sweat and tremble and I was sure I was going to faint. Then my fingers started to feel numb and tingly and things seemed unreal. It was so bad I wondered if I was dying and asked my husband to take me to the emergency room. By the time we got there (about 10 minutes) the worst of the attack was over and I just felt washed out” (Greist et al., 1986).

Phobias

Phobias are anxiety disorders in which an irrational fear causes the person to avoid some object, activity, or situation. Many people accept their phobias and live with them, but others are incapacitated by their efforts to avoid the feared situation. Marilyn, an otherwise healthy and happy 28-year-old, fears thunderstorms so intensely that she feels anxious as soon as a weather forecaster mentions possible storms later in the week. If her husband is away and a storm is forecast, she may stay with a close relative. During a storm, she hides from windows and buries her head to avoid seeing the lightning.

Other *specific phobias* may focus on animals, insects, heights, blood, or enclosed spaces (**FIGURE 66.1**). People avoid the stimulus that arouses the fear, hiding during thunderstorms or avoiding high places.

Not all phobias have such specific triggers. **Social anxiety disorder** (formerly called *social phobia*) is shyness taken to an extreme. Those with social anxiety disorder,

generalized anxiety disorder

an anxiety disorder in which a person is continually tense, apprehensive, and in a state of autonomic nervous system arousal.

panic disorder an anxiety disorder marked by unpredictable, minutes-long episodes of intense dread in which a person experiences terror and accompanying chest pain, choking, or other frightening sensations. Often followed by worry over a possible next attack.

phobia an anxiety disorder marked by a persistent, irrational fear and avoidance of a specific object, activity, or situation.

social anxiety disorder intense fear of social situations, leading to avoidance of such. (Formerly called *social phobia*.)

**Figure 66.1**

Some common and uncommon specific fears This Dutch national interview study identified the commonality of various specific fears. A strong fear becomes a phobia if it provokes a compelling but irrational desire to avoid the dreaded object or situation. (From Delpa et al., 2008.)

Martin Harvey/
Jupiterimages

an intense fear of being scrutinized by others, avoid potentially embarrassing social situations, such as speaking up, eating out, or going to parties—or will sweat or tremble when doing so.

Much as fretting over insomnia may, ironically, cause insomnia, so worries about anxiety—perhaps fearing another panic attack, or fearing anxiety-caused sweating in public—can amplify anxiety symptoms (Olatunji & Wolitzky-Taylor, 2009). People who have experienced several panic attacks may come to avoid situations where the panic has struck before. If the fear is intense enough, it may become **agoraphobia**, fear or avoidance of situations in which escape might be difficult or help unavailable when panic strikes. Given such fear, people may avoid being outside the home, in a crowd, on a bus, or on an elevator.

After spending five years sailing the world, Charles Darwin began suffering panic disorder at age 28. Because of the attacks, he moved to the country, avoided social gatherings, and traveled only in his wife’s company. But the relative seclusion did free him to focus on developing his evolutionary theory. “Even ill health,” he reflected, “has saved me from the distraction of society and its amusements” (quoted in Ma, 1997).

Obsessive-Compulsive Disorder

66-2 What is obsessive-compulsive disorder?

As with generalized anxiety and phobias, we can see aspects of **obsessive-compulsive disorder (OCD)** in our everyday behavior. We all may at times be obsessed with senseless or offensive thoughts that will not go away. Or we may engage in compulsive behaviors, perhaps lining up books and pencils “just so” before studying.

Obsessive thoughts and compulsive behaviors cross the fine line between normality and disorder when they persistently interfere with everyday living and cause distress. Checking to see you locked the door is normal; checking 10 times is not. Washing your hands is normal; washing so often that your skin becomes raw is not. (**TABLE 66.1** on the next page offers more examples.) At some time during their lives, often during their late teens or twenties, 2 to 3 percent of people cross that line from normal preoccupations and fussiness to debilitating disorder (Karno et al., 1988). Although the person knows them to be irrational, the anxiety-fueled obsessive thoughts become so haunting, the compulsive rituals so senselessly time-consuming, that effective functioning becomes impossible.

agoraphobia fear or avoidance of situations, such as crowds or wide open places, where one has felt loss of control and panic.

obsessive-compulsive disorder (OCD) a disorder characterized by unwanted repetitive thoughts (obsessions) and/or actions (compulsions).

Making everything perfect

Soccer star David Beckham has openly discussed his obsessive-compulsive tendencies, which have driven him to line up objects in pairs or to spend hours straightening furniture (Adams, 2011).

Stephen Dunn/Getty Images

Table 66.1 Common Obsessions and Compulsions Among Children and Adolescents With Obsessive-Compulsive Disorder

Thought or Behavior	Percentage Reporting Symptom
Obsessions (repetitive <i>thoughts</i>)	
Concern with dirt, germs, or toxins	40
Something terrible happening (fire, death, illness)	24
Symmetry, order, or exactness	17
Compulsions (repetitive <i>behaviors</i>)	
Excessive hand washing, bathing, toothbrushing, or grooming	85
Repeating rituals (in/out of a door, up/down from a chair)	51
Checking doors, locks, appliances, car brakes, homework	46

Source: Adapted from Rapoport, 1989.

posttraumatic stress disorder (PTSD) a disorder characterized by haunting memories, nightmares, social withdrawal, jumpy anxiety, numbness of feeling, and/or insomnia that lingers for four weeks or more after a traumatic experience.

OCD is more common among teens and young adults than among older people (Samuels & Nestadt, 1997). A 40-year follow-up study of 144 Swedish people diagnosed with the disorder found that, for most, the obsessions and compulsions had gradually lessened, though only 1 in 5 had completely recovered (Skoog & Skoog, 1999).

Posttraumatic Stress Disorder

66-3 What is posttraumatic stress disorder?

As an Iraq war soldier, Jesse “saw the murder of children, women. It was just horrible for anyone to experience.” After calling in a helicopter strike on one house where he had seen ammunition crates carried in, he heard the screams of children from within. “I didn’t know there were kids there,” he recalls. Back home in Texas, he suffered “real bad flashbacks” (Welch, 2005).

Our memories exist in part to protect us in the future. So there is biological wisdom in not being able to forget our most emotional or traumatic experiences—our greatest embarrassments, our worst accidents, our most horrid experiences. But sometimes, for some of us, the unforgettable takes over our lives. The complaints of battle-scarred

veterans such as Jesse—recurring haunting memories and nightmares, a numbed social withdrawal, jumpy anxiety, insomnia—are typical of what once was called “shellshock” or “battle fatigue” and now is called **posttraumatic stress disorder (PTSD)** (Babson & Feldner, 2010; Yufik & Simms, 2010). What defines and explains PTSD is less the event itself than the severity and persistence of the trauma memory (Rubin et al., 2008).

PTSD symptoms have also been reported by survivors of accidents, disasters, and violent and sexual assaults (including an estimated two-thirds of prostitutes) (Brewin et al., 1999; Farley et al., 1998; Taylor et al., 1998). A month after the 9/11 terrorist attacks, a survey of Manhattan residents indicated that 8.5 percent were suffering PTSD, most as a result of the attack (Galea et al., 2002). Among those living near the World Trade Center, 20 percent reported such telltale signs as nightmares, severe anxiety, and fear of public places (Susser et al., 2002).

Bringing the war home Nearly a quarter of a million Iraq and Afghanistan war veterans have been diagnosed with PTSD or traumatic brain injury (TBI). Many vets participate in an intensive recovery program using deep breathing, massage, and group and individual discussion techniques to treat their PTSD or TBI.

To pin down the frequency of this disorder, the U.S. Centers for Disease Control (1988) compared 7000 Vietnam combat veterans with 7000 noncombat veterans who served during the same years. On average, according to a reanalysis, 19 percent of all Vietnam veterans reported PTSD symptoms. The rate varied from 10 percent among those who had never seen combat to 32 percent among those who had experienced heavy combat (Dohrenwend et al., 2006). Similar variations in rates have been found among more recent combat veterans and among people who have experienced a natural disaster or have been kidnapped, held captive, tortured, or raped (Brewin et al., 2000; Brody, 2000; Kessler, 2000; Stone, 2005; Yaffe et al., 2010).

The toll seems at least as high for veterans of the Iraq war, where 1 in 6 U.S. combat infantry personnel has reported symptoms of PTSD, depression, or severe anxiety in the months after returning home (Hoge et al., 2006, 2007). In one study of 103,788 veterans returning from Iraq and Afghanistan, 1 in 4 was diagnosed with a psychological disorder, most frequently PTSD (Seal et al., 2007).

So what determines whether a person suffers PTSD after a traumatic event? Research indicates that the greater one's emotional distress during a trauma, the higher the risk for posttraumatic symptoms (Ozer et al., 2003). Among New Yorkers who witnessed the 9/11 attacks, PTSD was doubled for survivors who were inside rather than outside the World Trade Center (Bonanno et al., 2006). And the more frequent an assault experience, the more adverse the long-term outcomes tend to be (Golding, 1999). In the 30 years after the Vietnam war, veterans who came home with a PTSD diagnosis had twice the normal likelihood of dying (Crawford et al., 2009).

A sensitive limbic system seems to increase vulnerability, by flooding the body with stress hormones again and again as images of the traumatic experience erupt into consciousness (Kosslyn, 2005; Ozer & Weiss, 2004). Brain scans of PTSD patients suffering memory flashbacks reveal an aberrant and persistent right temporal lobe activation (Engdahl et al., 2010). Genes may also play a role. In one study, combat-exposed men had identical twins who did not experience combat. But these nonexposed co-twins still tended to share their brother's risk for cognitive difficulties, such as unfocused attention. Such findings suggest that some PTSD symptoms may actually be genetically predisposed (Gilbertson et al., 2006).

Some psychologists believe that PTSD has been overdiagnosed, due partly to a broadening definition of *trauma* (Dobbs, 2009; McNally, 2003). PTSD is actually infrequent, say those critics, and well-intentioned attempts to have people relive the trauma may exacerbate their emotions and pathologize normal stress reactions (Wakefield & Spitzer, 2002). "Debriefing" survivors right after a trauma by getting them to revisit the experience and vent emotions has actually proven generally ineffective and sometimes harmful (Bonanno et al., 2010).

Researchers have noted the impressive *survivor resiliency* of those who do *not* develop PTSD (Bonanno et al., 2010). About half of adults experience at least one traumatic event in their lifetime, but only about 1 in 10 women and 1 in 20 men develop PTSD (Olf et al., 2007; Ozer & Weiss, 2004; Tolin & Foa, 2006). More than 9 in 10 New Yorkers, although stunned and grief-stricken by 9/11, did *not* respond pathologically. By the following January, the stress symptoms of the rest had mostly subsided (Galea et al., 2002). Similarly, most combat-stressed veterans and most political dissidents who survive dozens of episodes of torture do not later exhibit PTSD (Mineka & Zinbarg, 1996). Likewise, the Holocaust survivors in 71 studies "showed remarkable resilience." Despite some lingering stress symptoms, most experienced essentially normal physical health and cognitive functioning (Barel et al., 2010).

Psychologist Peter Suedfeld (1998, 2000; Cassel & Suedfeld, 2006), who as a boy survived the Holocaust under deprived conditions while his mother died in Auschwitz, has documented the *resilience* of Holocaust survivors, most of whom have lived productive lives. "It is not always true that 'What doesn't kill you makes you stronger,' but it is often true," he reports. And "what doesn't kill you may reveal to you just how strong you really are."

Indeed, suffering can lead to "benefit finding" (Aspinwall & Tedeschi, 2010a,b; Helgeson et al., 2006), and to what Richard Tedeschi and Lawrence Calhoun (2004) call **posttraumatic growth**. Tedeschi and Calhoun have found that the struggle with challenging crises, such as

FYI

A \$125 million, five-year U.S. Army program is currently assessing the well-being of 800,000 soldiers and training them in emotional resilience (Stix, 2011).

posttraumatic growth positive psychological changes as a result of struggling with extremely challenging circumstances and life crises.

facing cancer, often leads people later to report an increased appreciation for life, more meaningful relationships, increased personal strength, changed priorities, and a richer spiritual life. This idea—that suffering has transformative power—is also found in Judaism, Christianity, Hinduism, Buddhism, and Islam. The idea is confirmed by research with ordinary people. Compared with those with traumatic life histories and with those unchallenged by any significant adversity, people whose life history includes *some* adversity tend to enjoy better mental health and well-being (Seery et al., 2010). Out of even our worst experiences some good can come. Like the body, the mind has great recuperative powers and may grow stronger with exertion.

Understanding Anxiety Disorders, OCD, and PTSD

66-4 How do the learning and biological perspectives explain anxiety disorders, OCD, and PTSD?

Anxiety is both a feeling and a cognition, a doubt-laden appraisal of one's safety or social skill. How do these anxious feelings and cognitions arise? Freud's psychoanalytic theory proposed that, beginning in childhood, people *repress* intolerable impulses, ideas, and feelings and that this submerged mental energy sometimes produces mystifying symptoms, such as anxiety. Today's psychologists have instead turned to two contemporary perspectives—learning and biological.

The Learning Perspective

CLASSICAL AND OPERANT CONDITIONING

When bad events happen unpredictably and uncontrollably, anxiety or other disorders often develop (Field, 2006b; Mineka & Oehlberg, 2008). Recall from Unit VI that dogs learn to fear neutral stimuli associated with shock and that infants come to fear furry objects associated with frightening noises. Using classical conditioning, researchers have also created chronically anxious, ulcer-prone rats by giving them unpredictable electric shocks (Schwartz, 1984). Like assault victims who report feeling anxious when returning to the scene of the crime, the rats become apprehensive in their lab environment. This link between conditioned fear and general anxiety helps explain why anxious or traumatized people are hyperattentive to possible threats, and how panic-prone people come to associate anxiety with certain cues (Bar-Haim et al., 2007; Bouton et al., 2001). In one survey, 58 percent of those with social anxiety disorder experienced their disorder after a traumatic event (Ost & Hugdahl, 1981).

Through conditioning, the short list of naturally painful and frightening events can multiply into a long list of human fears. My car was once struck by another whose driver missed a stop sign. For months afterward, I felt a twinge of unease when any car approached from a side street. Marilyn's phobia of thunderstorms may have been similarly conditioned during a terrifying or painful experience associated with a thunderstorm.

Two specific learning processes can contribute to these disorders. The first, *stimulus generalization*, occurs, for example, when a person attacked by a fierce dog later develops a fear of *all* dogs. The second learning process, *reinforcement*, helps maintain our phobias and compulsions after they arise. Avoiding or escaping the feared situation reduces anxiety, thus reinforcing the phobic behavior. Feeling anxious or fearing a panic attack, a person may go inside and be reinforced by feeling calmer (Antony et al., 1992). Compulsive behaviors operate similarly. If washing your hands relieves your feelings of anxiety, you may wash your hands again when those feelings return.

OBSERVATIONAL LEARNING

We may also learn fear through observational learning—by observing others' fears. Susan Mineka (1985, 2002) sought to explain why nearly all monkeys reared in the wild fear snakes, yet lab-reared monkeys do not. Surely, most wild monkeys do not actually suffer snake bites.

AP® Exam Tip

This is a good time to return to Unit VI and review the principles of classical and operant conditioning.

Do they learn their fear through observation? To find out, Mineka experimented with six monkeys reared in the wild (all strongly fearful of snakes) and their lab-reared offspring (virtually none of which feared snakes). After repeatedly observing their parents or peers refusing to reach for food in the presence of a snake, the younger monkeys developed a similar strong fear of snakes. When retested three months later, their learned fear persisted. Humans likewise learn fears by observing others (Olsson et al., 2007).

COGNITION

Observational learning is not the only cognitive influence on feelings of anxiety. As the next unit's discussion of cognitive-behavioral therapy illustrates, our interpretations and irrational beliefs can also cause feelings of anxiety. Whether we interpret the creaky sound in the old house simply as the wind or as a possible knife-wielding intruder determines whether we panic. People with anxiety disorder also tend to be *hypervigilant*. A pounding heart becomes a sign of a heart attack. A lone spider near the bed becomes a likely infestation. An everyday disagreement with a friend or boss spells possible doom for the relationship. Anxiety is especially common when people cannot switch off such intrusive thoughts and perceive a loss of control and sense of helplessness (Franklin & Foa, 2011).

The Biological Perspective

There is, however, more to anxiety, OCD, and PTSD than conditioning, observational learning, and cognition. The biological perspective can help us understand why few people develop lasting phobias after suffering traumas, why we learn some fears more readily, and why some individuals are more vulnerable.

NATURAL SELECTION

We humans seem biologically prepared to fear threats faced by our ancestors. Our phobias focus on such specific fears: spiders, snakes, and other animals; enclosed spaces and heights; storms and darkness. (Those fearless about these occasional threats were less likely to survive and leave descendants.) Thus, even in Britain, with only one poisonous snake species, people often fear snakes. And preschool children more speedily detect snakes in a scene than flowers, caterpillars, or frogs (LoBue & DeLoache, 2008). It is easy to condition and hard to extinguish fears of such "evolutionarily relevant" stimuli (Coelho & Purkis, 2009; Davey, 1995; Öhman, 2009).

Our modern fears can also have an evolutionary explanation. For example, a fear of flying may come from our biological predisposition to fear confinement and heights. Moreover, consider what people tend *not* to learn to fear. World War II air raids produced remarkably few lasting phobias. As the air blitzes continued, the British, Japanese, and German populations became not more panicked, but rather more indifferent to planes outside their immediate neighborhoods (Mineka & Zinbarg, 1996). Evolution has not prepared us to fear bombs dropping from the sky.

Just as our phobias focus on dangers faced by our ancestors, our compulsive acts typically exaggerate behaviors that contributed to our species' survival. Grooming gone wild becomes hair pulling. Washing up becomes ritual hand washing. Checking territorial boundaries becomes rechecking an already locked door (Rapoport, 1989).

GENES

Some people are more anxious than others. Genes matter. Pair a traumatic event with a sensitive, high-strung temperament and the result may be a new phobia (Belsky & Pluess, 2009). Some of us have genes that make us like orchids—fragile, yet capable of beauty under favorable circumstances. Others of us are like dandelions—hardy, and able to thrive in varied circumstances (Ellis & Boyce, 2008).

Among monkeys, fearfulness runs in families. Individual monkeys react more strongly to stress if their close biological relatives are anxiously reactive (Suomi, 1986).

Reuters/Mike Blakey/Landov

Fearless The biological perspective helps us understand why most people would be too afraid to try U.S. Olympic snowboarder Shaun White's tricks. White is less vulnerable to a fear of heights than most of us!

Genes influence disorders by regulating neurotransmitters. Some studies point to an anxiety gene that affects brain levels of *serotonin*, a neurotransmitter that influences sleep and mood (Canli, 2008). Other studies implicate genes that regulate the neurotransmitter *glutamate* (Lafleur et al., 2006; Welch et al., 2007). With too much glutamate, the brain's alarm centers become overactive.

THE BRAIN

Generalized anxiety, panic attacks, PTSD, and even obsessions and compulsions are manifested biologically as an overarousal of brain areas involved in impulse control and habitual behaviors. When the disordered brain detects that something is amiss, it seems to generate a mental hiccup of repeating thoughts or actions (Gehring et al., 2000). Brain scans of people with OCD reveal elevated activity in specific brain areas during behaviors such as compulsive hand washing, checking, ordering, or hoarding (Insel, 2010; Mataix-Cols et al., 2004, 2005). As **FIGURE 66.2** shows, the *anterior cingulate cortex*, a brain region that monitors our actions and checks for errors, seems especially likely to be hyperactive in those with OCD (Maltby et al., 2005). Fear-learning experiences that traumatize the brain can also create fear circuits within the amygdala (Etkin & Wager, 2007; Kolassa & Elbert, 2007; Maren, 2007). Some antidepressant drugs dampen this fear-circuit activity and its associated obsessive-compulsive behavior.

Fears can also be blunted by giving people drugs, such as propranolol or D-Cycloserine, as they recall and then rerecord ("reconsolidate") a traumatic experience (Kindt et al., 2009; Norberg, et al., 2008). Although they don't forget the experience, the associated emotion is largely erased.

Figure 66.2

An obsessive-compulsive brain Neuroscientists Nicholas Maltby, David Tolin, and their colleagues (2005) used functional MRI scans to compare the brains of those with and without OCD as they engaged in a challenging cognitive task. The scans of those with OCD showed elevated activity in the anterior cingulate cortex in the brain's frontal area (indicated by the yellow area on the far right).

Reprinted from *NeuroImage*, 24, Maltby, N., Tolin, D. F., Worhunsky, P., O'Keefe, T. M., & Kiehl, K. A. Dysfunctional action monitoring hyperactivates frontal-striatal circuits in obsessive-compulsive disorder. An event-related fMRI study, 495–503, 2005, with permission from Elsevier.

In humans, vulnerability to anxiety disorders rises when an afflicted relative is an identical twin (Hettema et al., 2001; Kendler et al., 1992, 1999, 2002a,b). Identical twins also may develop similar phobias, even when raised separately (Carey, 1990; Eckert et al., 1981). One pair of 35-year-old female identical twins independently became so afraid of water that each would wade in the ocean backward and only up to the knees.

Given the genetic contribution to anxiety disorders, researchers are now sleuthing the culprit genes. One research team has identified 17 genes that appear to be expressed with typical anxiety disorder symptoms (Hovatta et al., 2005). Other teams have found genes associated specifically with OCD (Dodman et al., 2010; Hu et al., 2006).

Before You Move On

▶ ASK YOURSELF

Can you recall a fear that you have learned? What role, if any, was played by fear conditioning and by observational learning?

▶ TEST YOURSELF

How do generalized anxiety disorder, panic disorder, phobias, obsessive-compulsive disorder, and posttraumatic stress disorder differ?

Answers to the Test Yourself questions can be found in Appendix E at the end of the book.

Module 66 Review

66-1 What are the different anxiety disorders?

- Anxious feelings and behaviors are classified as an *anxiety disorder* only when they form a pattern of distressing, persistent anxiety or maladaptive behaviors that reduce anxiety.
- People with *generalized anxiety disorder* feel persistently and uncontrollably tense and apprehensive, for no apparent reason.
- In the more extreme *panic disorder*, anxiety escalates into periodic episodes of intense dread.
- Those with a *phobia* may be irrationally afraid of a specific object, activity, or situation.
- Two other disorders (obsessive-compulsive disorder and posttraumatic stress disorder) involve anxiety (though they are classified separately from the anxiety disorders).

66-2 What is obsessive-compulsive disorder?

- Persistent and repetitive thoughts (obsessions) and actions (compulsions) characterize *obsessive-compulsive disorder (OCD)*.

66-3 What is posttraumatic stress disorder?

- Symptoms of *posttraumatic stress disorder (PTSD)* include four or more weeks of haunting memories, nightmares, social withdrawal, jumpy anxiety, and sleep problems following some traumatic experience.

66-4 How do the learning and biological perspectives explain anxiety disorders, OCD, and PTSD?

- The learning perspective views anxiety disorders, OCD, and PTSD as products of fear conditioning, stimulus generalization, fearful-behavior reinforcement, and observational learning of others' fears and cognitions (interpretations, irrational beliefs, and hypervigilance).
- The biological perspective considers the role that fears of life-threatening animals, objects, or situations played in natural selection and evolution; genetic predispositions for high levels of emotional reactivity and neurotransmitter production; and abnormal responses in the brain's fear circuits.

Multiple-Choice Questions

1. What do we call an anxiety disorder marked by a persistent, irrational fear and avoidance of a specific object, activity, or situation?
 - a. Obsessive-compulsive disorder
 - b. Phobia
 - c. Panic disorder
 - d. Generalized anxiety disorder
 - e. Posttraumatic stress disorder
2. A person troubled by repetitive thoughts or actions is most likely experiencing which of the following?
 - a. Generalized anxiety disorder
 - b. Posttraumatic stress disorder
 - c. Panic disorder
 - d. Obsessive-compulsive disorder
 - e. Fear conditioning
3. The key difference between obsessions and compulsions is that compulsions involve repetitive
 - a. thoughts.
 - b. experiences.
 - c. behaviors.
 - d. memories.
 - e. concerns.

Practice FRQs

1. Name the two contemporary perspectives used by psychologists to understand anxiety disorders. Then explain how or what psychologists study within each perspective.
2. Name and describe two anxiety disorders. **(4 points)**

Answer

1 point: The learning perspective

1 point: Psychologists using the learning perspective study fear conditioning, observational learning, or cognitive processes.

1 point: The biological perspective

1 point: Psychologists using the biological perspective study natural selection, genes, or the brain.

Module 67

Mood Disorders

Module Learning Objectives

- 67-1** Define *mood disorders*, and contrast major depressive disorder and bipolar disorder.
- 67-2** Describe how the biological and social-cognitive perspectives explain mood disorders.
- 67-3** Discuss the factors that affect suicide and self-injury, and identify important warning signs to watch for in suicide-prevention efforts.

- 67-1** What are mood disorders? How does major depressive disorder differ from bipolar disorder?

The emotional extremes of **mood disorders** come in two principal forms: (1) *major depressive disorder*, with its prolonged hopelessness and lethargy, and (2) *bipolar disorder* (formerly called *manic-depressive disorder*), in which a person alternates between depression and *mania*, an overexcited, hyperactive state.

mood disorders psychological disorders characterized by emotional extremes. See *major depressive disorder*, *mania*, and *bipolar disorder*.

Major Depressive Disorder

If you are like most high school students, at some time during this year—more likely the dark months of winter than the bright days of summer—you will probably experience some of depression’s symptoms. You may feel deeply discouraged about the future, dissatisfied with your life, or socially isolated. You may lack the energy to get things done or even to force yourself out of bed; be unable to concentrate, eat, or sleep normally; or even wonder if you would be better off dead. Perhaps academic success came easily to you in middle school, and now you find that disappointing grades jeopardize your goals. Maybe social stresses, such as feeling you don’t belong or experiencing the end of a romance, have plunged you into despair. And maybe brooding has at times only worsened your self-torment. Likely you think you are more alone in having such negative feelings than you really are (Jordan et al., 2011). In one survey of American high school students, 29 percent “felt so sad or hopeless almost every day for 2 or more weeks in a row that they stopped doing some usual activities” (CDC, 2008). In another national survey, of American collegians, 31 percent agreed when asked if in the past year they had at some time “felt so depressed that it was difficult to function” (ACHA, 2009). Misery has more company than most suppose.

Although phobias are more common, depression is the number-one reason people seek mental health services. At some point during their lifetime, depression plagues 12 percent of Canadian adults and 17 percent of U.S. adults (Holden, 2010; Patten et al., 2006). Moreover, it is the leading cause of disability worldwide (WHO, 2002). In any given year, a depressive episode plagues 5.8 percent of men and 9.5 percent of women, reports the World Health Organization.

“My life had come to a sudden stop. I was able to breathe, to eat, to drink, to sleep. I could not, indeed, help doing so; but there was no real life in me.” —LEO TOLSTOY, *MY CONFESSION*, 1887

“Depression . . . is well adapted to make a creature guard itself against any great or sudden evil.”
-CHARLES DARWIN, *THE LIFE AND LETTERS OF CHARLES DARWIN*, 1887

“If someone offered you a pill that would make you permanently happy, you would be well advised to run fast and run far. Emotion is a compass that tells us what to do, and a compass that is perpetually stuck on NORTH is worthless.” -DANIEL GILBERT, “THE SCIENCE OF HAPPINESS,” 2006

major depressive disorder

a mood disorder in which a person experiences, in the absence of drugs or another medical condition, two or more weeks with five or more symptoms, at least one of which must be either (1) depressed mood or (2) loss of interest or pleasure.

As anxiety is a response to the threat of future loss, depressed mood is often a response to past and current loss. About one in four people diagnosed with depression is debilitated by a significant loss, such as a loved one’s death, a ruptured marriage, or a lost job (Wakefield et al., 2007). To feel bad in reaction to profoundly sad events is to be in touch with reality. In such times, there is an up side to being down. Sadness is like a car’s low-fuel light—a signal that warns us to stop and take appropriate measures. Recall that, biologically speaking, life’s purpose is not happiness but survival and reproduction. Coughing, vomiting, swelling, and pain protect the body from dangerous toxins. Similarly, depression is a sort of psychic hibernation: It slows us down, defuses aggression, helps us let go of unattainable goals, and restrains risk taking (Andrews & Thomson, 2009a,b; Wrosch & Miller, 2009). To grind temporarily to a halt and ruminate, as depressed people do, is to reassess one’s life when feeling threatened, and to redirect energy in more promising ways (Watkins, 2008). Even mild sadness can improve people’s recall, make them more discerning, and help them make complex decisions (Forgas, 2009). There is sense to suffering.

But when does this response become seriously maladaptive? Joy, contentment, sadness, and despair are different points on a continuum, points at which any of us may be found at any given moment. The difference between a blue mood after bad news and a mood disorder is like the difference between gasping for breath after a hard run and being chronically short of breath.

Major depressive disorder occurs when at least five signs of depression last two or more weeks (**TABLE 67.1**). To sense what major depression feels like, suggest some clinicians, imagine combining the anguish of grief with the sluggishness of bad jet lag.

Adults diagnosed with *persistent depressive disorder* (also called *dysthymia*) experience a mildly depressed mood more often than not for at least two years (American Psychiatric Association, 2013). They also display at least two of the following symptoms:

1. Problems regulating appetite
2. Problems regulating sleep
3. Low energy
4. Low self-esteem
5. Difficulty concentrating and making decisions
6. Feelings of hopelessness

Table 67.1 Diagnosing Major Depressive Disorder

The DSM-5 classifies major depressive disorder as the presence of at least five of the following symptoms over a two-week period of time (including depressed mood or loss of interest or pleasure). The symptoms must cause near-daily distress or impairment and not be attributable to substance use or another medical or mental illness.

- Depressed mood most of the day
- Markedly diminished interest or pleasure in activities most of the day
- Significant weight loss or gain when not dieting, or significant decrease or increase in appetite
- Insomnia or sleeping too much
- Physical agitation or lethargy
- Fatigue or loss of energy
- Feeling worthless, or excessive or inappropriate guilt
- Problems in thinking, concentrating, or making decisions
- Recurrent thoughts of death and suicide

Bipolar Disorder

With or without therapy, episodes of major depression usually end, and people temporarily or permanently return to their previous behavior patterns. However, some people rebound to, or sometimes start with, the opposite emotional extreme—the euphoric, hyperactive, wildly optimistic state of **mania**. If depression is living in slow motion, mania is fast forward. Alternating between depression and mania (week to week, and not day to day or moment to moment) signals **bipolar disorder**.

Adolescent mood swings, from rage to bubbly, can, when prolonged, produce a bipolar diagnosis. Between 1994 and 2003, U.S. National Center for Health Statistics annual physician surveys revealed an astonishing 40-fold increase in diagnoses of bipolar disorder in those 19 and under—from an estimated 20,000 to 800,000 (Carey, 2007; Flora & Bobby, 2008; Moreno et al., 2007). The new popularity of the diagnosis, given in two-thirds of the cases to boys, has been a boon to companies whose drugs are prescribed to lessen mood swings. The DSM-5 will likely reduce the number of child and adolescent bipolar diagnoses, by classifying as *disruptive mood dysregulation disorder* some of those with emotional volatility (Miller, 2010).

During the manic phase, people with bipolar disorder are typically overtalkative, overactive, and elated (though easily irritated); have little need for sleep; and show fewer sexual inhibitions. Speech is loud, flighty, and hard to interrupt. They find advice irritating. Yet they need protection from their own poor judgment, which may lead to reckless spending or unsafe sex.

In milder forms, mania’s energy and free-flowing thinking does fuel creativity. George Frideric Handel, who may have suffered from a mild form of bipolar disorder, composed his nearly four-hour-long *Messiah* (1742) during three weeks of intense, creative energy (Keynes, 1980). Robert Schumann composed 51 musical works during two years of mania (1840 and 1849) and none during 1844, when he was severely depressed (Slater & Meyer, 1959). Those who rely on precision and logic, such as architects, designers, and journalists, suffer bipolar disorder less often than do those who rely on emotional expression and vivid imagery (Ludwig, 1995). Composers, artists, poets, novelists, and entertainers seem especially prone (Jamison, 1993, 1995; Kaufman & Baer, 2002; Ludwig, 1995).

Creativity and bipolar disorder

There are many creative artists, composers, writers, and musical performers with bipolar disorder. Madeleine L'Engle wrote in *A Circle of Quiet* (1972): “All the people in history, literature, art, whom I most admire: Mozart, Shakespeare, Homer, El Greco, St. John, Chekhov, Gregory of Nyssa, Dostoevsky, Emily Brontë: not one of them would qualify for a mental-health certificate.”

FYI

For some people suffering depressive disorders or bipolar disorder, symptoms may have a *seasonal pattern*. Depression may regularly return each fall or winter, and mania (or a reprieve from depression) may dependably arrive with spring. For many others, winter darkness simply means more blue moods. When asked “Have you cried today?” Americans have agreed more often in the winter.

	Percentage who cried	
	Men	Women
August	4%	7%
December	8%	21%

Source: Time/CNN survey, 1994.

mania a mood disorder marked by a hyperactive, wildly optimistic state.

bipolar disorder a mood disorder in which a person alternates between the hopelessness and lethargy of depression and the overexcited state of mania. (Formerly called *manic-depressive disorder*.)

Life after depression Writer J. K. Rowling reports suffering acute depression—a “dark time,” with suicidal thoughts—between ages 25 and 28. It was, she said, a “terrible place” that did, however, form a foundation that allowed her “to come back stronger” (McLaughlin, 2010).

It is as true of emotions as of everything else: What goes up comes down. Before long, the elated mood either returns to normal or plunges into a depression. Though bipolar disorder is much less common than major depressive disorder, it is often more dysfunctional, claiming twice as many lost workdays yearly (Kessler et al., 2006). Among adults, it afflicts men and women about equally.

Understanding Mood Disorders

67-2 How do the biological and social-cognitive perspectives explain mood disorders?

In thousands of studies, psychologists have been accumulating evidence to help explain mood disorders and suggest more effective ways to treat and prevent them. Researcher Peter Lewinsohn and his colleagues (1985, 1998, 2003) summarized the facts that any theory of depression must explain, including the following:

- **Many behavioral and cognitive changes accompany depression.** People trapped in a depressed mood are inactive and feel unmotivated. They are sensitive to negative happenings (Peckham et al., 2010). They more often recall negative information. They expect negative outcomes (my team will lose, my grades will fall, my love will fail). When the mood lifts, these behavioral and cognitive accompaniments disappear. Nearly half the time, people also exhibit symptoms of another disorder, such as anxiety or substance use disorder.
- **Depression is widespread.** Its commonality suggests that its causes, too, must be common.
- **Women’s risk of major depression is nearly double men’s.** When Gallup in 2009 asked more than a quarter-million Americans if they had ever been diagnosed with depression, 13 percent of men and 22 percent of women said they had (Pelham, 2009). This gender gap has been found worldwide (**FIGURE 67.1**). The trend begins in adolescence; preadolescent girls are not more depression-prone than are boys (Hyde et al., 2008).

Figure 67.1

Gender and major depression Interviews with 89,037 adults in 18 countries (10 shown here) confirm what many smaller studies have found: Women’s risk of major depression is nearly double that of men’s.

The factors that put women at risk for depression (genetic predispositions, child abuse, low self-esteem, marital problems, and so forth) similarly put men at risk (Kendler et al., 2006). Yet women are more vulnerable to disorders involving internalized states, such as depression, anxiety, and inhibited sexual desire. Men’s disorders tend to be more external—alcohol use disorder, antisocial conduct, lack of impulse control. When women get sad, they often get sadder than men do. When men get mad, they often get madder than women do.

- **Most major depressive episodes self-terminate.** Although therapy often helps and tends to speed recovery, most people suffering major depression eventually return to normal even without professional help. The plague of depression comes and, a few weeks or months later, it goes, though for about half of people it eventually

recurs (Burcusa & Iacono, 2007; Curry et al., 2011; Hardeveld et al., 2010). For only about 20 percent is the condition chronic (Klein, 2010). On average, patients with major depression today will spend about three-fourths of the next decade in a normal, nondepressed state (Furukawa et al., 2009). Recovery is more likely to be permanent the later the first episode strikes, the longer the person stays well, the fewer the previous episodes, the less stress experienced, and the more social support received (Belsher & Costello, 1988; Fergusson & Woodward, 2002; Kendler et al., 2001).

The emotional lives of men and women?

- ***Stressful events related to work, marriage, and close relationships often precede depression.***

A family member's death, a job loss, a marital crisis, or a physical assault increase one's risk of depression (Kendler et al., 2008; Monroe & Reid, 2009; Orth et al., 2009). If stress-related anxiety is a "crackling, menacing brushfire," notes biologist Robert Sapolsky (2003), "depression is a suffocating heavy blanket thrown on top of it." One long-term study (Kendler, 1998) tracked rates of depression in 2000 people. The risk of depression ranged from less than 1 percent among those who had experienced no stressful life event in the preceding month to 24 percent among those who had experienced three such events in that month.

- ***With each new generation, depression is striking earlier (now often in the late teens) and affecting more people, with the highest rates in developed countries among young adults.*** This is true in Canada, the United States, England, France, Germany, Italy, Lebanon, New Zealand, Puerto Rico, and Taiwan (Collishaw et al., 2007; Cross-National Collaborative Group, 1992; Kessler et al., 2010; Twenge et al., 2008). In one study, 12 percent of Australian adolescents reported symptoms of depression (Sawyer et al., 2000). Most hid it from their parents; almost 90 percent of those parents perceived their depressed teen as *not* suffering depression. In North America, today's young adults are three times more likely than their grandparents to report having recently—or ever—suffered depression (despite the grandparents' many more years of being at risk). The increase appears partly authentic, but it may also reflect today's young adults' greater willingness to disclose depression.

Today's researchers propose biological and cognitive explanations of depression, often combined in a biopsychosocial approach.

The Biological Perspective

GENETIC INFLUENCES

Mood disorders run in families. As one researcher noted, emotions are "postcards from our genes" (Plotkin, 1994). The risk of major depression and bipolar disorder increases if you have a parent or sibling with the disorder (Sullivan et al., 2000). If one identical twin is diagnosed with major depressive disorder, the chances are about 1 in 2 that at some time the other twin will be, too. If one identical twin has bipolar disorder, the chances are 7 in 10 that the other twin will at some point be diagnosed similarly. Among fraternal twins, the corresponding odds are just under 2 in 10 (Tsuang & Faraone, 1990). The greater similarity among identical twins holds even among twins raised apart (DiLalla et al., 1996). Summarizing the major twin studies, one research team estimated the heritability (extent to which individual differences are attributable to genes) of major depression at 37 percent (**FIGURE 67.2** on the next page).

"I see depression as the plague of the modern era." -LEWIS JUDD, FORMER CHIEF, NATIONAL INSTITUTE OF MENTAL HEALTH, 2000

Figure 67.2**The heritability of various psychological disorders**

Researchers Joseph Bienvenu, Dimitry Davydow, and Kenneth Kendler (2011) aggregated data from studies of identical and fraternal twins to estimate the heritability of bipolar disorder, schizophrenia, anorexia nervosa, major depressive disorder, and generalized anxiety disorder.

Moreover, adopted people who suffer a mood disorder often have close biological relatives who suffer mood disorders, develop alcohol use disorder, or commit suicide (Wender et al., 1986). (Close-up: Suicide and Self-Injury reports other research findings.)

Suicide and Self-Injury

67-3

What factors affect suicide and self-injury, and what are some of the important warning signs to watch for in suicide prevention efforts?

““But life, being weary of these worldly bars, / Never lacks power to dismiss itself.” -WILLIAM SHAKESPEARE, JULIUS CAESAR, 1599

Each year nearly 1 million despairing people worldwide will elect a permanent solution to what might have been a temporary problem. Comparing the suicide rates of different groups, researchers have found

- **national differences:** Britain's, Italy's, and Spain's suicide rates are little more than half those of Canada, Australia, and the United States. Austria's and Finland's are about double (WHO, 2011). Within Europe, people in the most suicide-prone country (Belarus) have been 16 times more likely to kill themselves than those in the least (Georgia).
- **racial differences:** Within the United States, Whites kill themselves twice as often as Blacks (AAS, 2010).
- **gender differences:** Women are much more likely than men to attempt suicide (WHO, 2011). But men are two to four times more likely (depending on the country) to actually end their lives. Men use more lethal methods, such as firing a bullet into the head, the method of choice in 6 of 10 U.S. suicides.
- **age differences and trends:** In late adulthood, rates increase, peaking in middle age and beyond. In the last half of the twentieth century, the global rate of annual suicide deaths nearly doubled (WHO, 2008).

- **other group differences:** Suicide rates are much higher among the rich, the nonreligious, and those who are single, widowed, or divorced (Hoyer & Lund, 1993; Stack, 1992; Stengel, 1981). When facing an unsupportive environment, including family or peer rejection, gay and lesbian youth are at increased risk of attempting suicide (Goldfried, 2001; Haas et al., 2011; Hatzenbuehler, 2011).
- **day of the week differences:** 25 percent of suicides occur on Wednesdays (Kposowa & D'Auria, 2009).

The risk of suicide is at least five times greater for those who have been depressed than for the general population (Bostwick & Pankratz, 2000). People seldom commit suicide while in the depths of depression, when energy and initiative are lacking. The risk increases when they begin to rebound and become capable of following through. Among people with alcohol use disorder, 3 percent die by suicide. This rate is roughly 100 times greater than the rate for people without alcohol use disorder (Murphy & Wetzel, 1990; Sher, 2006).

Because suicide is so often an impulsive act, environmental barriers (such as jump barriers on high bridges and the unavailability of loaded guns) can reduce suicides (Anderson, 2008). Although common sense might suggest that a determined person would simply find another way to complete the act, such restrictions give time for self-destructive impulses to subside.

Social suggestion may trigger suicide. Following highly publicized suicides and TV programs featuring suicide, known suicides increase. So do fatal auto and private airplane “accidents.” One six-year study tracked suicide cases among all 1.2 million people who lived in metropolitan Stockholm at any time during the 1990s

(continued)

Close-up (continued)

(Hedström et al., 2008). Men exposed to a family suicide were 8 times more likely to commit suicide than were nonexposed men. Although that phenomenon may be partly attributable to family genes, shared genetic predispositions do not explain why men exposed to a co-worker's suicide were 3.5 times more likely to commit suicide, compared with nonexposed men.

Suicide is not necessarily an act of hostility or revenge. The elderly sometimes choose death as an alternative to current or future suffering. In people of all ages, suicide may be a way of switching off unendurable pain and relieving a perceived burden on family members. "People desire death when two fundamental needs are frustrated to the point of extinction," notes Thomas Joiner (2006, p. 47): "The need to belong with or connect to others, and the need to feel effective with or to influence others." Suicidal urges typically arise when people feel disconnected from others, and a burden to them (Joiner, 2010), or when they feel defeated and trapped by an inescapable situation (Taylor et al., 2011). Thus, suicide rates increase a bit during economic recessions (Luo et al., 2011). Suicidal thoughts also may increase when people are driven to reach a goal or standard—to become thin or straight or rich—and find it unattainable (Chatard & Selimbegović, 2011).

In hindsight, families and friends may recall signs they believe should have forewarned them—verbal hints, giving possessions away, or withdrawal and preoccupation with death. To judge from surveys of 84,850 people across 17 nations, about 9 percent of people at some point in their lives have thought seriously of suicide. About 30 percent of these (3 percent of people) actually attempt it (Nock et al., 2008). For only about 1 in 25 does the attempt become their final act (AAS, 2009). Of those who die, one-third had tried to kill themselves previously. Most discussed it beforehand. So, if a friend talks suicide to you, it's important to listen and to direct the person to professional help. Anyone who threatens suicide is at least sending a signal of feeling desperate or despondent.

NONSUICIDAL SELF-INJURY

Suicide is not the only way to send a message or deal with distress. Some people, especially adolescents and young adults, may engage in *nonsuicidal self-injury (NSSI)* (**FIGURE 67.3**). Such behavior includes cutting or burning the skin, hitting oneself, pulling hair out, inserting objects under the nails or skin, and self-administered tattooing (Fikke et al., 2011).

Why do people hurt themselves? Those who do so tend to be less able to tolerate emotional distress, are extremely self-critical, and often have poor communication and problem-solving skills (Nock, 2010). They engage in NSSI to

- gain relief from intense negative thoughts through the distraction of pain,
- ask for help and gain attention,
- relieve guilt by self-punishment
- get others to change their negative behavior (bullying, criticism), or
- to fit in with a peer group.

Does NSSI lead to suicide? Usually not. Those who engage in NSSI are typically *suicide gesturers*, not *suicide attempters* (Nock & Kessler, 2006). Suicide gesturers engage in NSSI as a desperate but non-life-threatening form of communication or when they are feeling overwhelmed. But NSSI has been shown to be a risk factor for future suicide attempts (Wilkinson & Goodyer, 2011). If people do not get help, their nonsuicidal behavior may escalate to suicidal ideation and finally, to attempted suicide.

Figure 67.3

Rates of nonfatal self-injury in the U.S. Self-injury rates peak higher for females than for males (CDC, 2009).

To tease out the genes that put people at risk for depression, some researchers have turned to *linkage analysis*. After finding families in which the disorder appears across several generations, geneticists examine DNA from affected and unaffected family members, looking for differences. Linkage analysis points us to a chromosome neighborhood, note behavior genetics researchers Robert Plomin and Peter McGuffin (2003); “a house-to-house search is then needed to find the culprit gene.” Such studies are reinforcing the view that depression is a complex condition. Many genes work together, producing a mosaic of small effects that interact with other factors to put some people at greater risk. If the culprit gene variations can be identified—with chromosome 3 genes implicated in separate British and American studies (Breen et al., 2011; Pergadia et al., 2011)—they may open the door to more effective drug therapy.

THE DEPRESSED BRAIN

Using modern technology, researchers are also gaining insight into brain activity during depressed and manic states, and into the effects of certain neurotransmitters during these states. One study gave 13 elite Canadian swimmers the wrenching experience of watching a video of the swim in which they failed to make the Olympic team or failed at the Olympic games (Davis et al., 2008). Functional MRI scans showed the disappointed swimmers experiencing brain activity patterns akin to those of patients with depressed moods.

Many studies have found diminished brain activity during slowed-down depressive states, and more activity during periods of mania (**FIGURE 67.4**). The left frontal lobe and an adjacent brain reward center are active during positive emotions, but less active during depressed states (Davidson et al., 2002; Heller et al., 2009). In one study of people with severe depression, MRI scans also found their frontal lobes 7 percent smaller than normal (Coffey et al., 1993). Other studies show that the hippocampus, the memory-processing center linked with the brain’s emotional circuitry, is vulnerable to stress-related damage.

Bipolar disorder likewise correlates with brain structure. Neuroscientists have found structural differences, such as decreased axonal white matter or enlarged fluid-filled ventricles, in the brains of people with bipolar disorder (Kempton et al., 2008; van der Schot et al., 2009).

Neurotransmitter systems influence mood disorders. Norepinephrine, which increases arousal and boosts mood, is scarce during depression and overabundant during mania. (Drugs that alleviate mania reduce norepinephrine.) Many people with a history of depression also have a history of habitual smoking, and smoking increases one’s risk for future depression (Pasco et al. 2008). This may indicate an attempt to self-medicate with inhaled nicotine, which can temporarily increase norepinephrine and boost mood (HMHL, 2002b).

Researchers are also exploring a second neurotransmitter, serotonin (Carver et al., 2008). One well-publicized study of New Zealand young adults found that the recipe for depression combined two necessary ingredients—significant life stress plus a variation on a serotonin-controlling gene (Caspi et al., 2003; Moffitt et al., 2006). Depression arose from the interaction of an adverse environment plus a genetic susceptibility, but not from either alone. But stay tuned: The story of gene-environment interactions is still being written, as other researchers debate the reliability of this result (Caspi et al., 2010; Karg et al., 2011; Munafò et al., 2009; Risch et al., 2009; Uher & McGuffin, 2010).

AP® Exam Tip

You can review brain scanning techniques, neurotransmitters, and brain structures in Unit III.

Figure 67.4

The ups and downs of bipolar disorder

These top-facing PET scans show that brain energy consumption rises and falls with the patient’s emotional switches. Areas where the brain rapidly consumes glucose are shown in red in these images.

Drugs that relieve depression tend to increase norepinephrine or serotonin supplies by blocking either their reuptake (as Prozac, Zoloft, and Paxil do with serotonin) or their chemical breakdown. Repetitive physical exercise, such as jogging, reduces depression as it increases serotonin (Ilardi, 2009; Jacobs, 1994). Boosting serotonin may promote recovery from depression by stimulating hippocampus neuron growth (Airan et al., 2007; Jacobs et al., 2000).

What's good for the heart is also good for the brain and mind. People who eat a heart-healthy "Mediterranean diet" (heavy on vegetables, fish, and olive oil) have a comparatively low risk of developing heart disease, late-life cognitive decline, and depression—all of which are associated with inflammation (Dowlati et al., 2010; Sánchez-Villegas et al., 2009; Tangney et al., 2011). Excessive alcohol use also correlates with depression—mostly because alcohol misuse leads to depression (Fergusson et al., 2009).

The Social-Cognitive Perspective

Depression is a whole-body disorder. Biological influences contribute to depression but don't fully explain it. The social-cognitive perspective explores the roles of thinking and acting.

Depressed people view life through the dark glasses of low self-esteem (Orth et al., 2009). Their intensely negative assumptions about themselves, their situation, and their future lead them to magnify bad experiences and minimize good ones. Listen to Norman, a Canadian college professor, recalling his depression:

I [despaired] of ever being human again. I honestly felt subhuman, lower than the lowest vermin. Furthermore, I was self-deprecatory and could not understand why anyone would want to associate with me, let alone love me. . . . I was positive that I was a fraud and a phony and that I didn't deserve my Ph.D. I didn't deserve to have tenure; I didn't deserve to be a Full Professor. . . . I didn't deserve the research grants I had been awarded; I couldn't understand how I had written books and journal articles. . . . I must have conned a lot of people. (Endler, 1982, pp. 45–49)

Research reveals how *self-defeating beliefs* and a *negative explanatory style* feed depression's vicious cycle.

NEGATIVE THOUGHTS AND NEGATIVE MOODS INTERACT

Self-defeating beliefs may arise from *learned helplessness*. As we saw in Module 29, both dogs and humans act depressed, passive, and withdrawn after experiencing uncontrollable painful events. Learned helplessness is more common in women than in men, and women may respond more strongly to stress (Hankin & Abramson, 2001; Mazure et al., 2002; Nolen-Hoeksema, 2001, 2003). For example, 38 percent of women and 17 percent of men entering U. S. colleges and universities report feeling at least occasionally "overwhelmed by all I have to do" (Pryor et al., 2006). (Men report spending more of their time in "light anxiety" activities such as sports, TV watching, and partying, possibly avoiding activities that might make them feel overwhelmed.) This may help explain why, beginning in their early teens, women are nearly twice as vulnerable to depression. Susan Nolen-Hoeksema (2003) believed women's higher risk of depression relates to what she described as their tendency to *overthink*, to ruminate. **Rumination**—staying focused on a problem (thanks to the continuous firing of a frontal lobe area that sustains attention)—can be adaptive (Altamirano et al., 2010; Andrews & Thomson, 2009a,b). But when it is relentless, self-focused rumination diverts us from thinking about other life tasks and produces a negative emotional inertia (Kuppens et al., 2010).

But why do life's unavoidable failures lead only some people to become depressed? The answer lies partly in their *explanatory style*—who or what they blame for their failures (or credit for their successes). Think of how you might feel if you failed a test. If you can externalize the blame ("What an unfair test!"), you are more likely to feel angry. If you blame yourself, you probably will feel stupid and depressed.

Michael Marsland

Susan Nolen-Hoeksema

(1959–2013) "This epidemic of morbid meditation is a disease that women suffer much more than men. Women can ruminate about anything and everything—our appearance, our families, our career, our health." (*Women Who Think Too Much: How to Break Free of Overthinking and Reclaim Your Life*, 2003)

rumination compulsive fretting; *overthinking* about our problems and their causes.

"I have learned to accept my mistakes by referring them to a personal history which was not of my making." -B. F. SKINNER (1983)

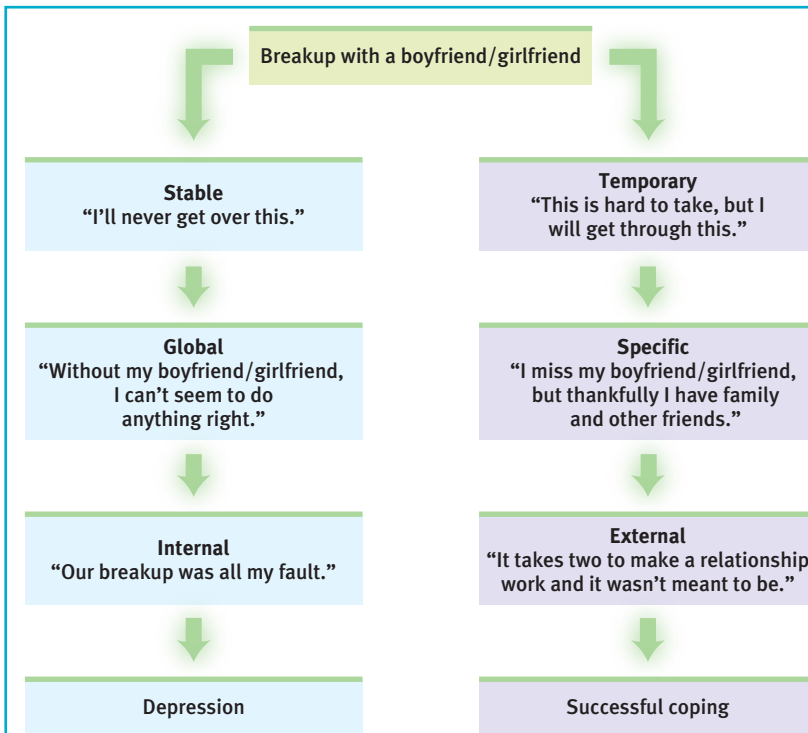

Figure 67.5

Explanatory style and depression

After a negative experience, a depression-prone person may respond with a negative explanatory style.

first episode of major depression, as did only 1 percent of those who began college with an optimistic thinking style.

Seligman (1991, 1995) has contended that depression is common among young Westerners because the rise of individualism and the decline of commitment to religion and family have forced young people to take personal responsibility for failure or rejection. In non-Western cultures, where close-knit relationships and cooperation are the norm, major depression is less common and less tied to self-blame over personal failure (WHO, 2004a). In Japan, for example, depressed people instead tend to report feeling shame over letting others down (Draguns, 1990a).

So it is with depressed people, who tend to explain bad events in terms that are *stable* ("It's going to last forever"), *global* ("It's going to affect everything I do"), and *internal* ("It's all my fault") (FIGURE 67.5). Depression-prone people respond to bad events in an especially self-focused, self-blaming way (Mor & Winquist, 2002; Pyszczynski et al., 1991; Wood et al., 1990a,b). Their self-esteem fluctuates more rapidly up with boosts and down with threats (Butler et al., 1994).

The result of these pessimistic, overgeneralized, self-blaming attributions may be a depressing sense of hopelessness (Abramson et al., 1989; Panzarella et al., 2006). As Martin Seligman has noted, "A recipe for severe depression is preexisting pessimism encountering failure" (1991, p. 78). What then might we expect of new college students who are not depressed but do exhibit a pessimistic explanatory style? Lauren Alloy and her collaborators (1999) monitored Temple University and University of Wisconsin students every 6 weeks for 2.5 years. Among those identified as having a pessimistic thinking style, 17 percent had a

There is, however, a chicken-and-egg problem with the social-cognitive explanation of depression. Self-defeating beliefs, negative attributions, and self-blame *coincide* with a depressed mood and are *indicators* of depression. But do they *cause* depression, any more than a speedometer's reading causes a car's speed? Before or after being depressed, people's thoughts are less negative. Perhaps this is because, as we noted in our discussion of state-dependent memory (Module 32), a depressed mood triggers negative thoughts. If you temporarily put people in a bad or sad mood, their memories, judgments, and expectations suddenly become more pessimistic.

DEPRESSION'S VICIOUS CYCLE

Depression, as we have seen, is often brought on by stressful experiences—losing a job, getting divorced or rejected, suffering physical trauma—by anything that disrupts our sense of who we are and why we are worthy human beings. This disruption in turn leads

"Man never reasons so much and becomes so introspective as when he suffers, since he is anxious to get at the cause of his sufferings." -LUIGI PIRANDELLO, *SIX CHARACTERS IN SEARCH OF AN AUTHOR*, 1922

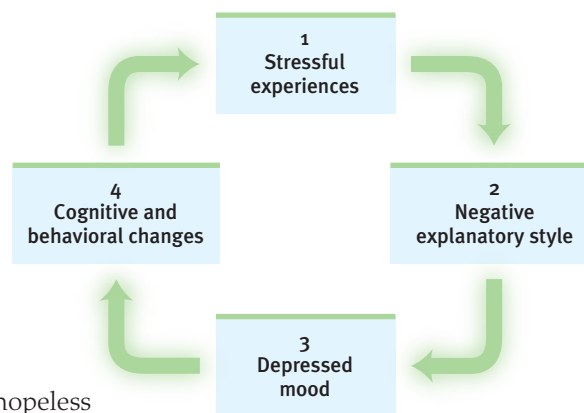

to brooding, which amplifies negative feelings. But being withdrawn, self-focused, and complaining can by itself elicit rejection (Furr & Funder, 1998; Gotlib & Hammen, 1992). In one study, researchers Stephen Strack and James Coyne (1983) noted that “depressed persons induced hostility, depression, and anxiety in others and got rejected. Their guesses that they were not accepted were not a matter of cognitive distortion.” Indeed, people in the throes of depression are at high risk for divorce, job loss, and other stressful life events. Weary of the person’s fatigue, hopeless attitude, and lethargy, a spouse may threaten to leave or a boss may begin to question the person’s competence. (This provides another example of genetic-environmental interaction: People genetically predisposed to depression more often experience depressing events.) The losses and stress only serve to compound the original depression. Rejection and depression feed each other. Misery may love another’s company, but company does not love another’s misery.

We can now assemble some of the pieces of the depression puzzle (**FIGURE 67.6**): (1) Negative, stressful events interpreted through (2) a ruminating, pessimistic explanatory style create (3) a hopeless, depressed state that (4) hampers the way the person thinks and acts. This, in turn, fuels (1) negative, stressful experiences such as rejection.

None of us is immune to the dejection, diminished self-esteem, and negative thinking brought on by rejection or defeat. As Edward Hirt and his colleagues (1992) demonstrated, even small losses can temporarily sour our thinking. They studied some avid Indiana University basketball fans who seemed to regard the team as an extension of themselves. After the fans watched their team lose or win, the researchers asked them to predict the team’s future performance and their own. After a loss, the morose fans offered bleaker assessments not only of the team’s future but also of their own likely performance at throwing darts, solving anagrams, and getting a date. When things aren’t going our way, it may seem as though they never will.

It is a cycle we can all recognize. Bad moods feed on themselves: When we *feel* down, we *think* negatively and remember bad experiences. On the brighter side, we can break the cycle of depression at any of these points—by moving to a different environment, by reversing our self-blame and negative attributions, by turning our attention outward, or by engaging in more pleasant activities and more competent behavior.

Winston Churchill called depression a “black dog” that periodically hounded him. Poet Emily Dickinson was so afraid of bursting into tears in public that she spent much of her adult life in seclusion (Patterson, 1951). As each of these lives reminds us, people can and do struggle through depression. Most regain their capacity to love, to work, and even to succeed at the highest levels.

**Figure 67.6****The vicious cycle of depressed thinking**

Cognitive therapists attempt to break this cycle, as we will see in Module 71, by changing the way depressed people process events. Psychiatrists attempt to alter with medication the biological roots of persistently depressed moods.

“Some cause happiness wherever they go; others, whenever they go.” -IRISH WRITER OSCAR WILDE (1854–1900)

Before You Move On

▶ ASK YOURSELF

Has your high school experience been a challenging time for you? What advice would you have for other students about to enter high school?

▶ TEST YOURSELF

What is the most common psychological disorder? What is the disorder for which people most often seek treatment?

Answers to the Test Yourself questions can be found in Appendix E at the end of the book.

Module 67 Review

67-1 What are mood disorders? How do major depressive disorder differ from bipolar disorder?

- *Mood disorders* are characterized by emotional extremes.
- A person with *major depressive disorder* experiences two or more weeks of seriously depressed moods and feelings of worthlessness, and takes little interest in, and derives little pleasure from, most activities.
- A person with the less common condition of *bipolar disorder* experiences not only depression but also *mania*—episodes of hyperactive and wildly optimistic, impulsive behavior.

67-2 How do the biological and social-cognitive perspectives explain mood disorders?

- The biological perspective on depression focuses on genetic predispositions and on abnormalities in brain structures and function (including those found in neurotransmitter systems).
- The social-cognitive perspective views depression as an ongoing cycle of stressful experiences (interpreted through negative beliefs, attributions, and memories) leading to negative moods and actions and fueling new stressful experiences.

67-3 What factors affect suicide and self-injury, and what are some of the important warning signs to watch for in suicide-prevention efforts?

- Suicide rates differ by nation, race, gender, age group, income, religious involvement, marital status, and (for gay and lesbian youth) social support structure.
- Those with depression are more at risk for suicide than others are, but social suggestion, health status, and economic and social frustration are also contributing factors.
- Environmental barriers (such as jump barriers) are effective in preventing suicides.
- Forewarnings of suicide may include verbal hints, giving away possessions, withdrawal, preoccupation with death, and discussing one's own suicide.
- Nonsuicidal self-injury (NSSI) does not usually lead to suicide but may escalate to suicidal thoughts and acts if untreated.
- People who engage in NSSI do not tolerate stress well and tend to be self-critical, with poor communication and problem-solving skills.

Multiple-Choice Questions

- Which of the following is NOT a symptom of major depressive disorder?
 - Weight gain or loss
 - Auditory hallucinations
 - Sleep disturbance
 - Inappropriate guilt
 - Problems concentrating
- Which of the following is true of depression?
 - Depression usually develops during middle age.
 - Depression usually happens without major cognitive or behavioral changes.
 - A major depressive episode usually gets worse and worse unless it's treated.
 - True depression is usually not related to stress in one's work or relationships.
 - Compared with men, nearly twice as many women have been diagnosed with depression.
- Which of the following is true of suicide?
 - Marijuana use is related to suicide, but alcohol use is not.
 - Women are more likely to end their lives than men.
 - Suicide is a bigger problem among the poor than the rich.
 - In the United States, suicide is more common among Whites than Blacks.
 - Married individuals are more likely to commit suicide than single people.

4. Based on brain scans, which of the following is true of brain function and mood?
- The brain is more active during manic episodes and less active during depressive episodes.
 - The brain is less active during manic episodes and more active during depressive episodes.
 - There is no consistent relationship between brain activity and mood.
 - The brain is more active than normal during both manic and depressive episodes.
 - The brain is less active than normal during both manic and depressive episodes.
5. Xavier, who has a negative explanatory style, is most likely to get depressed after failing a math test if he believes that he failed because
- he is not good at math and never will be.
 - his teacher made it impossible to learn the material.
 - he was sick on the day he took the test.
 - his parents have been putting too much pressure on him and he panicked on the test.
 - the testing room was very hot and stuffy.

Practice FRQs

1. Christina became depressed after being laid off from her job. Her therapist thinks it's because she has a stable, global, and internal explanatory style. Illustrate each of these three attributes by writing a possible thought Christina might have for each one.
2. Identify and describe the two major symptoms of bipolar disorder.

(4 points)

Answer

1 point: Stable thought (For example, "I have always had trouble holding down a job").

1 point: Global thought (For example, "Everything in my life is messed up").

1 point: Internal thought (For example, "It's all my fault I lost this job").

Module 68

Schizophrenia

Module Learning Objectives

- 68-1** Describe the patterns of thinking, perceiving, and feeling that characterize schizophrenia.
- 68-2** Contrast chronic and acute schizophrenia.
- 68-3** Discuss how brain abnormalities and viral infections help explain schizophrenia.
- 68-4** Discuss the evidence for genetic influences on schizophrenia, and describe some factors that may be early warning signs of schizophrenia in children.

schizophrenia a psychological disorder characterized by delusions, hallucinations, disorganized speech, and/or diminished or inappropriate emotional expression.

psychosis a psychological disorder in which a person loses contact with reality, experiencing irrational ideas and distorted perceptions.

delusions false beliefs, often of persecution or grandeur, that may accompany psychotic disorders.

AP® Exam Tip

It is common for the AP® exam to measure your awareness of various “media myths” about psychology. One of the most common of these myths is that schizophrenia means “split personality” or “multiple personality.” Read this section carefully to achieve an accurate understanding of what schizophrenia is—and isn’t.

Imagine trying to communicate with Maxine, a young woman with schizophrenia whose thoughts spill out in no logical order. Her biographer, Susan Sheehan (1982, p. 25), observed her saying aloud to no one in particular, “This morning, when I was at Hillside [Hospital], I was making a movie. I was surrounded by movie stars. . . . I’m Mary Poppins. Is this room painted blue to get me upset? My grandmother died four weeks after my eighteenth birthday.”

Nearly 1 in 100 people (about 60 percent men) develop schizophrenia, with an estimated 24 million across the world suffering from this dreaded disorder (Abel et al., 2010; WHO, 2011).

Symptoms of Schizophrenia

- 68-1** What patterns of thinking, perceiving, and feeling characterize schizophrenia?

Literally translated, **schizophrenia** means “split mind.” It refers *not* to a multiple-personality split but rather to a split from reality that shows itself in disturbed perceptions, disorganized thinking and speech, and diminished, inappropriate emotions. As such, it is the chief example of a **psychosis**, a *psychotic disorder* marked by irrationality and lost contact with reality.

Disorganized Thinking and Disturbed Perceptions

As Maxine’s strange monologue illustrates, the thinking of a person with schizophrenia is fragmented, bizarre, and often distorted by false beliefs called **delusions** (“I’m Mary Poppins”). Those with *paranoid* tendencies are particularly prone to delusions of persecution. Even within sentences, jumbled ideas may create what is called *word salad*. One young man

begged for “a little more allegro in the treatment,” and suggested that “liberatory movement with a view to the widening of the horizon” will “ergo extort some wit in lectures.”

A person with schizophrenia may have **hallucinations** (sensory experiences without sensory stimulation). They may see, feel, taste, or smell things that are not there. Most often, however, the hallucinations are auditory, frequently voices making insulting remarks or giving orders. The voices may tell the patient that she is bad or that she must burn herself with a cigarette lighter. Imagine your own reaction if a dream broke into your waking consciousness. When the unreal seems real, the resulting perceptions are at best bizarre, at worst terrifying.

Disorganized thoughts may result from a breakdown in *selective attention*. Recall from Module 16 that we normally have a remarkable capacity for giving our undivided attention to one set of sensory stimuli while filtering out others. Those with schizophrenia cannot do this. Thus, irrelevant, minute stimuli, such as the grooves on a brick or the inflections of a voice, may distract their attention from a bigger event or a speaker’s meaning. As one former patient recalled, “What had happened to me . . . was a breakdown in the filter, and a hodge-podge of unrelated stimuli were distracting me from things which should have had my undivided attention” (MacDonald, 1960, p. 218). This selective-attention difficulty is but one of dozens of cognitive differences associated with schizophrenia (Reichenberg & Harvey, 2007).

Diminished and Inappropriate Emotions

The expressed emotions of schizophrenia are often utterly inappropriate, split off from reality (Kring & Caponigro, 2010). Maxine laughed after recalling her grandmother’s death. On other occasions, she cried when others laughed, or became angry for no apparent reason. Others with schizophrenia lapse into an emotionless state of *flat affect*. Most also have difficulty perceiving facial emotions and reading others’ states of mind (Green & Horan, 2010; Kohler et al., 2010).

Motor behavior may also be inappropriate. Some perform senseless, compulsive acts, such as continually rocking or rubbing an arm. Others, who exhibit *catatonia*, may remain motionless for hours and then become agitated.

As you can imagine, such disorganized thinking, disturbed perceptions, and inappropriate emotions profoundly disrupt social relationships and make it difficult to hold a job. Even those with *dissociative identity disorder*, which we’ll discuss later in this unit, may continue to function in everyday life, but less so those with schizophrenia. During their most severe periods, those with schizophrenia live in a private inner world, preoccupied with illogical ideas and unreal images. Given a supportive environment and medication, over 40 percent of schizophrenia patients will have periods of a year or more of normal life experience (Jobe & Harrow, 2010). Many others remain socially withdrawn and isolated or rejected throughout much of their lives (Hooley, 2010).

Onset and Development of Schizophrenia

68-2 How do chronic and acute schizophrenia differ?

Schizophrenia typically strikes as young people are maturing into adulthood. Although it only afflicts 1 in 100 people, it knows no national boundaries, and it affects both males and females—though men tend to be struck earlier, more severely, and slightly more often (Aleman et al., 2003; Picchioni & Murray, 2007).

Art by someone diagnosed with schizophrenia

Commenting on the kind of artwork shown here (from Craig Geiser’s 2010 art exhibit in Michigan), poet and art critic John Ashbery wrote: “The lure of the work is strong, but so is the terror of the unanswerable riddles it proposes.”

AP® Exam Tip

Are you clear about the difference between delusions and hallucinations? Delusions are false *thoughts*. Hallucinations are false *sensory experiences*.

“When someone asks me to explain schizophrenia I tell them, you know how sometimes in your dreams you are in them yourself and some of them feel like real nightmares? My schizophrenia was like I was walking through a dream. But everything around me was real. At times, today’s world seems so boring and I wonder if I would like to step back into the schizophrenic dream, but then I remember all the scary and horrifying experiences.” -STUART EMMONS, WITH CRAIG GEISER, KALMAN J. KAPLAN, AND MARTIN HARROW, *LIVING WITH SCHIZOPHRENIA*, 1997

hallucination false sensory experience, such as seeing something in the absence of an external visual stimulus.

For some, schizophrenia will appear suddenly, seemingly as a reaction to stress. For others, as was the case with Maxine, schizophrenia develops gradually, emerging from a long history of social inadequacy and poor school performance (MacCabe et al., 2008). No wonder those predisposed to schizophrenia often end up in the lower socioeconomic levels, or even homeless.

We have thus far described schizophrenia as if it were a single disorder. Actually, it varies. Schizophrenia patients with *positive symptoms* may experience hallucinations, talk in disorganized and deluded ways, and exhibit inappropriate laughter, tears, or rage. Those with *negative symptoms* have toneless voices, expressionless faces, or mute and rigid bodies. Thus, positive symptoms are the *presence* of inappropriate behaviors, and negative symptoms are the *absence* of appropriate behaviors.

When schizophrenia is a slow-developing process (called *chronic*, or *process*, *schizophrenia*), recovery is doubtful (WHO, 1979). Those with chronic schizophrenia often exhibit the persistent and incapacitating negative symptom of social withdrawal (Kirkpatrick et al., 2006). Men, whose schizophrenia develops on average four years earlier than women's, more often exhibit negative symptoms and chronic schizophrenia (Räsänen et al., 2000). When previously well-adjusted people develop schizophrenia rapidly (called *acute*, or *reactive*, *schizophrenia*) following particular life stresses, recovery is much more likely. They more often have the positive symptoms that are responsive to drug therapy (Fenton & McGlashan, 1991, 1994; Fowles, 1992).

Understanding Schizophrenia

Schizophrenia is not only the most dreaded psychological disorder but also one of the most heavily researched. Most of the new research studies link it with brain abnormalities and genetic predispositions. Schizophrenia is a disease of the brain manifest in symptoms of the mind.

Brain Abnormalities

68-3

How do brain abnormalities and viral infections help explain schizophrenia?

Might imbalances in brain chemistry underlie schizophrenia? Scientists have long known that strange behavior can have strange chemical causes. The saying “mad as a hatter” refers to the psychological deterioration of British hatmakers whose brains, it was later discovered, were slowly poisoned as they moistened the brims of mercury-laden felt hats with their tongue and lips (Smith, 1983). As we saw in Module 25, scientists are clarifying the mechanism by which chemicals such as LSD produce hallucinations. These discoveries hint that schizophrenia symptoms might have a biochemical key.

DOPAMINE OVERACTIVITY

Researchers discovered one such key when they examined schizophrenia patients' brains after death and found an excess of receptors for *dopamine*—a sixfold excess for the so-called D4 dopamine receptor (Seeman et al., 1993; Wong et al., 1986). They now speculate that such a hyper-responsive dopamine system may intensify brain signals in schizophrenia, creating positive symptoms such as hallucinations and paranoia (Grace, 2010). As we might therefore expect, drugs that block dopamine receptors often lessen these symptoms; drugs that increase dopamine levels, such as amphetamines and cocaine, sometimes intensify them (Seeman, 2007; Swerdlow & Koob, 1987).

FYI

Most schizophrenia patients smoke, often heavily. Nicotine apparently stimulates certain brain receptors, which helps focus attention (Diaz et al., 2008; Javitt & Coyle, 2004).

ABNORMAL BRAIN ACTIVITY AND ANATOMY

Modern brain-scanning techniques reveal that many people with chronic schizophrenia have abnormal activity in multiple brain areas. Some have abnormally low brain activity in the frontal lobes, which are critical for reasoning, planning, and problem solving (Morey et al., 2005; Pettegrew et al., 1993; Resnick, 1992). People diagnosed with schizophrenia also display a noticeable decline in the brain waves that reflect synchronized neural firing in the frontal lobes (Spencer et al., 2004; Symond et al., 2005). Out-of-sync neurons may disrupt the integrated functioning of neural networks, possibly contributing to schizophrenia symptoms.

One study took PET scans of brain activity while people were hallucinating (Silbersweig et al., 1995). When participants heard a voice or saw something, their brain became vigorously active in several core regions, including the thalamus, a structure deep in the brain that filters incoming sensory signals and transmits them to the cortex. Another PET scan study of people with paranoia found increased activity in the amygdala, a fear-processing center (Epstein et al., 1998).

Many studies have found enlarged, fluid-filled areas and a corresponding shrinkage and thinning of cerebral tissue in people with schizophrenia (Goldman et al., 2009; Wright et al., 2000). Some studies have even found such abnormalities in the brains of people who would *later* develop this disorder and in their close relatives (Karlsgodt et al., 2010). The greater the brain shrinkage, the more severe the thought disorder (Collinson et al., 2003; Nelson et al., 1998; Shenton, 1992). One smaller-than-normal area is the cortex. Another is the corpus callosum connection between the two hemispheres (Arnone et al., 2008). Another is the thalamus, which may explain why people with schizophrenia have difficulty filtering sensory input and focusing attention (Andreasen et al., 1994; Ellison-Wright et al., 2008). The bottom line of various studies is that schizophrenia involves not one isolated brain abnormality but problems with several brain regions and their interconnections (Andreasen, 1997, 2001).

Naturally, scientists wonder what causes these abnormalities. Some point to mishaps during prenatal development or delivery (Fatemi & Folsom, 2009; Walker et al., 2010). Risk factors for schizophrenia include low birth weight, maternal diabetes, older paternal age, and oxygen deprivation during delivery (King et al., 2010). Famine may also increase risks. People conceived during the peak of the Dutch wartime famine later displayed a doubled rate of schizophrenia, as did those conceived during the famine that occurred from 1959 to 1961 in eastern China (St. Clair et al., 2005; Susser et al., 1996).

MATERNAL VIRUS DURING MIDPREGNANCY

Consider another possible culprit: a midpregnancy viral infection that impairs fetal brain development (Patterson, 2007). Can you imagine some ways to test this fetal-virus idea? Scientists have asked the following:

- *Are people at increased risk of schizophrenia if, during the middle of their fetal development, their country experienced a flu epidemic?* The repeated answer is *Yes* (Mednick et al., 1994; Murray et al., 1992; Wright et al., 1995).
- *Are people born in densely populated areas, where viral diseases spread more readily, at greater risk for schizophrenia?* The answer, confirmed in a study of 1.75 million Danes, is *Yes* (Jablensky, 1999; Mortensen, 1999).
- *Are those born during the winter and spring months—after the fall-winter flu season—also at increased risk?* Although the increase is small, just 5 to 8 percent, the answer is again *Yes* (Fox, 2010; Torrey et al., 1997, 2002).

Chris Mueller/Redux

Studying the neurophysiology of schizophrenia Psychiatrist E. Fuller Torrey has collected the brains of hundreds of those who died as young adults and suffered disorders such as schizophrenia and bipolar disorder.

- *In the Southern Hemisphere, where the seasons are the reverse of the Northern Hemisphere, are the months of above-average schizophrenia births similarly reversed?* Again, the answer is *Yes*, though somewhat less so. In Australia, for example, people born between August and October are at greater risk—*unless* they migrated from the Northern Hemisphere, in which case their risk is greater if they were born between January and March (McGrath et al., 1995, 1999).
- *Are mothers who report being sick with influenza during pregnancy more likely to bear children who develop schizophrenia?* In one study of nearly 8000 women, the answer was *Yes*. The schizophrenia risk increased from the customary 1 percent to about 2 percent—but only when infections occurred during the second trimester (Brown et al., 2000). Maternal influenza infection during pregnancy also affects brain development in monkeys (Short et al., 2010).
- *Does blood drawn from pregnant women whose offspring develop schizophrenia show higher-than-normal levels of antibodies that suggest a viral infection?* In one study of 27 women whose children later developed schizophrenia, the answer was *Yes* (Buka et al., 2001). And the answer was again *Yes* in a huge California study, which collected blood samples from some 20,000 pregnant women during the 1950s and 1960s (Brown et al., 2004). Another study found traces of a specific retrovirus (HERV) in nearly half of people with schizophrenia and virtually none in healthy people (Perron et al., 2008).

These converging lines of evidence suggest that fetal-virus infections play a contributing role in the development of schizophrenia. They also strengthen the recommendation that “women who will be more than three months pregnant during the flu season” have a flu shot (CDC, 2003).

Why might a second-trimester maternal flu bout put fetuses at risk? Is it the virus itself? The mother’s immune response to it? Medications taken (Wyatt et al., 2001)? Does the infection weaken the brain’s supportive glial cells, leading to reduced synaptic connections (Moises et al., 2002)? In time, answers may become available.

Genetic Factors

68-4

Are there genetic influences on schizophrenia? What factors may be early warning signs of schizophrenia in children?

Figure 68.1

Risk of developing schizophrenia

The lifetime risk of developing schizophrenia varies with one’s genetic relatedness to someone having this disorder. Across countries, barely more than 1 in 10 fraternal twins, but some 5 in 10 identical twins, share a schizophrenia diagnosis. (Adapted from Gottesman, 2001.)

Fetal-virus infections do appear to increase the odds that a child will develop schizophrenia. But this theory cannot tell us why only 2 percent of women who catch the flu during their second trimester of pregnancy bear children who develop schizophrenia. Might people also inherit a predisposition to this disorder? The evidence strongly suggests that, *Yes*, some do. The nearly 1-in-100 odds of any person’s being diagnosed with schizophrenia become about 1 in 10 among those whose sibling or parent has the disorder, and close to 1 in 2 if the affected sibling is an identical twin (**FIGURE 68.1**). Although only a dozen or so such cases

are on record, the co-twin of an identical twin with schizophrenia retains that 1-in-2 chance even when the twins are reared apart (Plomin et al., 1997).

Remember, though, that identical twins also share a prenatal environment. About two-thirds also share a placenta and the blood it supplies; the other one-third have two single placentas. If an identical twin has schizophrenia, the co-twin’s chances of being similarly afflicted are 6 in 10 if they shared a placenta. If they had separate placentas, as do fraternal twins, the chances are only 1 in 10 (Davis et al., 1995a,b; Phelps et al., 1997). Twins who share a placenta are more likely to

experience the same prenatal viruses. So it is possible that shared germs as well as shared genes produce identical twin similarities.

Adoption studies, however, confirm that the genetic link is real (Gottesman, 1991). Children adopted by someone who develops schizophrenia seldom “catch” the disorder. Rather, adopted children have an elevated risk if a *biological* parent is diagnosed with schizophrenia.

With the genetic factor established, researchers are now sleuthing specific genes that, in some combination, might predispose schizophrenia-inducing brain abnormalities (Levinson et al., 2011; Mitchell & Porteous, 2011; Vacic et al., 2011; Wang et al., 2010). (It is not our genes but our brains that directly control our behavior.) Some of these genes influence the effects of dopamine and other neurotransmitters in the brain. Others affect the production of *myelin*, a fatty substance that coats the axons of nerve cells and lets impulses travel at high speed through neural networks.

Although the genetic contribution to schizophrenia is beyond question, the genetic formula is not as straightforward as the inheritance of eye color. Genome studies of thousands of individuals with and without schizophrenia indicate that schizophrenia is influenced by many genes, each with very small effects (International Schizophrenia Consortium, 2009; Pogue-Geile & Yokley, 2010). Recall from Module 14 that *epigenetic* (literally “in addition to genetic”) factors influence gene expression. Like hot water activating the tea bag, environmental factors such as prenatal viral infections, nutritional deprivation, and maternal stress can “turn on” the genes that predispose schizophrenia. Identical twins’ differing histories in the womb and beyond explain why only one of them may show differing gene expressions (Walker et al., 2010). As we have so often seen, nature and nurture interact. Neither hand claps alone.

Thanks to our expanding understanding of genetic and brain influences on maladies such as schizophrenia, the general public more and more attributes psychiatric disorders to biological factors (Pescosolido et al., 2010). In 2007, one privately funded new research center announced its ambitious aim: “To unambiguously diagnose patients with psychiatric disorders based on their DNA sequence in 10 years’ time” (Holden, 2007). In 2010, \$120 million in start-up funding launched a bold new effort to study the neuroscience and genetics of schizophrenia and other psychiatric disorders (Kaiser, 2010). So, can scientists develop genetic tests that reveal who is at risk? If so, will people in the future subject their embryos to genetic testing (and gene repair or abortion) if they are at risk for this or some other psychological or physical malady? Might they take their egg and sperm to a genetics lab for screening before combining them to produce an embryo? Or will children be tested for genetic risks and given appropriate preventive treatments? In this brave new twenty-first-century world, such questions await answers.

Psychological Factors

If prenatal viruses and genetic predispositions do not, by themselves, cause schizophrenia, neither do family or social factors alone. It remains true, as Susan Nicol and Irving Gottesman (1983) noted almost three decades ago, that “no environmental causes have been discovered that will invariably, or even with moderate probability, produce schizophrenia in persons who are not related to” a person with schizophrenia.

Hoping to identify environmental triggers of schizophrenia, several investigators are following the development of “high-risk” children, such as those born to a parent with schizophrenia or exposed to prenatal risks (Freedman et al., 1998; Olin & Mednick, 1996; Susser, 1999). One study followed 163 teens and early-twenties adults who had two relatives with schizophrenia. During the 2.5-year study, the 20 percent who developed schizophrenia displayed some tendency to withdraw socially and behave oddly before the onset of

Schizophrenia in identical twins

When twins differ, only the one afflicted with schizophrenia typically has enlarged, fluid-filled cranial cavities (right) (Suddath et al., 1990). The difference between the twins implies some nongenetic factor, such as a virus, is also at work.

Both photos: From Daniel Weinberger, M.D., CBDB, NIMH

FYI

The odds of any four people picked at random all being diagnosed with schizophrenia are 1 in 100 million. But genetically identical sisters Nora, Iris, Myra, and Hester Genain all have the disease. Two of the sisters have more severe forms of the disorder than the others, suggesting the influence of environmental as well as biological factors.

the disorder (Johnstone et al., 2005). By comparing the experiences of high-risk and low-risk children who do versus do not develop schizophrenia, researchers have so far pinpointed the following possible early warning signs:

- A mother whose schizophrenia was severe and long-lasting
- Birth complications, often involving oxygen deprivation and low birth weight
- Separation from parents
- Short attention span and poor muscle coordination
- Disruptive or withdrawn behavior
- Emotional unpredictability
- Poor peer relations and solo play

* * *

Most of us can relate more easily to the ups and downs of mood disorders than to the strange thoughts, perceptions, and behaviors of schizophrenia. Sometimes our thoughts do jump around, but in the absence of disorder we do not talk nonsensically. Occasionally we feel unjustly suspicious of someone, but we do not fear that the world is plotting against us. Often our perceptions err, but rarely do we see or hear things that are not there. We have felt regret after laughing at someone's misfortune, but we rarely giggle in response to bad news. At times we just want to be alone, but we do not live in social isolation. However, millions of people around the world do talk strangely, suffer delusions, hear nonexistent voices, see things that are not there, laugh or cry at inappropriate times, or withdraw into private imaginary worlds. The quest to solve the cruel puzzle of schizophrenia therefore continues, and more vigorously than ever.

Before You Move On

▶ ASK YOURSELF

Do you think the media accurately portray the behavior of people suffering from schizophrenia? Why or why not?

▶ TEST YOURSELF

How do researchers believe that biological and environmental factors interact in the onset of schizophrenia?

Answers to the Test Yourself questions can be found in Appendix E at the end of the book.

Module 68 Review

68-1 What patterns of thinking, perceiving, and feeling characterize schizophrenia?

- *Schizophrenia* is a disorder that typically strikes during late adolescence, affects men slightly more than women, and seems to occur in all cultures.
- Symptoms are disorganized and delusional thinking, disturbed perceptions, and diminished or inappropriate emotions.
- *Delusions* are false beliefs; *hallucinations* are sensory experiences without sensory stimulation.

68-2 How do chronic and acute schizophrenia differ?

- Schizophrenia symptoms may be positive (the presence of inappropriate behaviors) or negative (the absence of appropriate behaviors).
- In chronic (or process) schizophrenia, the disorder develops gradually and recovery is doubtful.
- In acute (or reactive) schizophrenia, the onset is sudden, in reaction to stress, and the prospects for recovery are brighter.

68-3 How do brain abnormalities and viral infections help explain schizophrenia?

- People with schizophrenia have increased dopamine receptors, which may intensify brain signals, creating positive symptoms such as hallucinations and paranoia.
- Brain abnormalities associated with schizophrenia include enlarged, fluid-filled cerebral cavities and corresponding decreases in the cortex.
- Brain scans reveal abnormal activity in the frontal lobes, thalamus, and amygdala.
- Interacting malfunctions in multiple brain regions and their connections may produce schizophrenia's symptoms.
- Possible contributing factors include viral infections or famine conditions during the mother's pregnancy and low weight or oxygen deprivation at birth.

68-4 Are there genetic influences on schizophrenia? What factors may be early warning signs of schizophrenia in children?

- Twin and adoption studies indicate that the predisposition to schizophrenia is inherited, and environmental factors influence gene expression to enable this disorder, which is found worldwide.
- No environmental causes invariably produce schizophrenia.
- Possible early warning signs of later development of schizophrenia include both biological factors (a mother with severe and long-lasting schizophrenia; oxygen deprivation and low weight at birth; short attention span and poor muscle coordination) as well as psychological factors (disruptive or withdrawn behavior; emotional unpredictability; poor peer relations and solo play).

Multiple-Choice Questions

1. Which of the following is the best term or phrase for a false belief, often of persecution, that may accompany psychotic disorders?
 - a. Psychosis
 - b. Schizophrenia
 - c. Delusion
 - d. Split mind
 - e. Dissociative identity disorder
2. Which of the following is true?
 - a. Those born during winter and spring are less likely to develop schizophrenia later in life.
 - b. People born in densely populated areas are less likely to develop schizophrenia later in life.
 - c. Fetuses exposed to flu virus are more likely to develop schizophrenia later in life.
 - d. Maternal influenza during pregnancy does not affect brain development in monkeys.
 - e. The retrovirus HERV is found more often in people who do not develop schizophrenia.
3. According to research, which of the following has been identified as an early warning sign of schizophrenia?
 - a. Emotional predictability
 - b. Poor peer relations and solo play
 - c. Long attention span
 - d. Good muscle coordination
 - e. High birth weight

Practice FRQs

1. Name three possible warning signs of schizophrenia.
2. Name and explain two brain abnormalities that help us understand schizophrenia.

Answer

(4 points)

Score 1 point for any of the following (up to 3) possibilities.

- A mother whose schizophrenia was severe and long-lasting
- Birth complications, often involving oxygen deprivation and low weight
- Separation from parents
- Short attention span and poor muscle coordination
- Disruptive or withdrawn behavior
- Emotional unpredictability
- Poor peer relations and solo play

Module 69

Other Disorders

Module Learning Objectives

- 69-1** Describe somatic symptom and related disorders.
- 69-2** Describe dissociative disorders, and discuss why they are controversial.
- 69-3** Explain how anorexia nervosa, bulimia nervosa, and binge-eating disorder demonstrate the influence of psychological and genetic forces.
- 68-4** Contrast the three clusters of personality disorders, and describe the behaviors and brain activity that characterize the antisocial personality.

Somatic Symptom and Related Disorders

- 69-1** What are somatic symptom and related disorders?

Among the most common problems bringing people into doctors' offices are "medically unexplained illnesses" (Johnson, 2008). Ellen becomes dizzy and nauseated in the late afternoon—shortly before she expects her husband home. Neither her primary care physician nor the neurologist he sent her to could identify a physical cause. They suspect her symptoms have an unconscious psychological origin, possibly triggered by her mixed feelings about her husband. In a **somatic symptom disorder** such as Ellen's, the distressing symptoms take a somatic (bodily) form without apparent physical causes. One person may have a variety of complaints—vomiting, dizziness, blurred vision, difficulty in swallowing. Another may experience severe and prolonged pain.

Culture has a big effect on people's physical complaints and how they explain them (Kirmayer & Sartorius, 2007). In China, psychological explanations of anxiety and depression are socially less acceptable than in many Western countries, and people less often express the emotional aspects of distress. The Chinese appear more sensitive to—and more willing to report—the physical symptoms of their distress (Ryder et al., 2008). Mr. Wu, a 36-year-old technician in Hunan, illustrates one of China's most common psychological disorders (Spitzer & Skodol, 2000). He finds work difficult because of his insomnia, fatigue, weakness, and headaches. Chinese herbs and Western medicines provide no relief. To his Chinese clinician, who treats the bodily symptoms, he seems not so much depressed as exhausted. Similar, generalized bodily complaints have often been observed in African cultures (Binitie, 1975).

somatic symptom disorder a psychological disorder in which the symptoms take a somatic (bodily) form without apparent physical cause. (See *conversion disorder* and *illness anxiety disorder*.)

conversion disorder a disorder in which a person experiences very specific genuine physical symptoms for which no physiological basis can be found. (Also called *functional neurological symptom disorder*.)

illness anxiety disorder a disorder in which a person interprets normal physical sensations as symptoms of a disease. (Formerly called *hypochondriasis*.)

dissociative disorders disorders in which conscious awareness becomes separated (dissociated) from previous memories, thoughts, and feelings.

Even to people in the West, somatic symptoms are familiar. To a lesser extent, we have all experienced inexplicable physical symptoms under stress. It is little comfort to be told that the problem is “all in your head.” Although the symptoms may be psychological in origin, they are nevertheless genuinely felt.

One rare type of disorder, more common in Freud’s day than in ours, is **conversion disorder** (also known as *functional neurological symptom disorder*), so called because anxiety presumably is converted into a physical symptom. (As we noted in Module 55, Freud’s effort to treat and understand psychological disorders stemmed from his puzzlement over ailments that had no physiological basis.) A patient with a conversion disorder might, for example, lose sensation in a way that makes no neurological sense. Yet the physical symptoms would be real; sticking pins in the affected area would produce no response. Other conversion disorder symptoms might be unexplained paralysis, blindness, or an inability to swallow. In each case, the person would be strangely indifferent to the problem.

As you can imagine, somatic symptom and related disorders send people not to a psychologist or psychiatrist but to a physician. This is especially true of those who experience **illness anxiety disorder** (formerly called *hypochondriasis*). In this relatively common disorder, people interpret normal sensations (a stomach cramp today, a headache tomorrow) as symptoms of a dreaded disease. Sympathy or temporary relief from everyday demands may reinforce such complaints. No amount of reassurance by any physician convinces the patient that the trivial symptoms do not reflect a serious illness. So the patient moves on to another physician, seeking and receiving more medical attention—but failing to confront the disorder’s psychological root.

Before You Move On

▶ ASK YOURSELF

Can you recall (as most people can) times when you have fretted needlessly over a normal bodily sensation?

▶ TEST YOURSELF

What does *somatic* mean?

Answers to the Test Yourself questions can be found in Appendix E at the end of the book.

Dissociative Disorders

69-2 What are dissociative disorders, and why are they controversial?

Among the most bewildering disorders are the rare **dissociative disorders**. These are disorders of consciousness, in which a person appears to experience a sudden loss of memory or change in identity, often in response to an overwhelmingly stressful situation. Chris Sizemore’s story, told in the book and movie *The Three Faces of Eve*, gave early visibility to what is now called *dissociative identity disorder*. One Vietnam veteran who was haunted by his comrades’ deaths, and who had left his World Trade Center office shortly before the 9/11 attack, disappeared en route to work one day and was discovered six months later in a Chicago homeless shelter, reportedly with no memory of his identity or family (Stone, 2006). In such *fugue state* cases, the person’s conscious awareness is said to *dissociate* (become separated) from painful memories, thoughts, and feelings. (Note that this explanation presumes the existence of repressed memories, which, as we noted in Modules 33 and 56, have been questioned by memory researchers.)

Dissociation itself is not so rare. Now and then, many people may have a sense of being unreal, of being separated from their body, of watching themselves as if in a movie.

Sometimes we may say, “I was not myself at the time.” Perhaps you can recall getting up to go somewhere and ending up at some unintended location while your mind was preoccupied elsewhere. Or perhaps you can play a well-practiced tune on a guitar or piano while talking to someone. Facing trauma, dissociative detachment may actually protect a person from being overwhelmed by emotion.

Dissociative Identity Disorder

A massive dissociation of self from ordinary consciousness characterizes those with **dissociative identity disorder (DID)**, in which two or more distinct identities are said to alternately control the person’s behavior. Each personality has its own voice and mannerisms. Thus the person may be prim and proper one moment, loud and flirtatious the next. Typically, the original personality denies any awareness of the other(s).

People diagnosed with DID (formerly called *multiple personality disorder*) are usually not violent, but cases have been reported of dissociations into a “good” and a “bad” (or aggressive) personality—a modest version of the Dr. Jekyll/Mr. Hyde split immortalized in Robert Louis Stevenson’s story. One unusual case involved Kenneth Bianchi, accused in the “Hillside Strangler” rapes and murders of 10 California women. During a hypnosis session with Bianchi, psychologist John Watkins (1984) “called forth” a hidden personality: “I’ve talked a bit to Ken, but I think that perhaps there might be another part of Ken that . . . maybe feels somewhat differently from the part that I’ve talked to. . . . Would you talk with me, Part, by saying, ‘I’m here?’” Bianchi answered “Yes” and then claimed to be “Steve.”

Speaking as Steve, Bianchi stated that he hated Ken because Ken was nice and that he (Steve), aided by a cousin, had murdered women. He also claimed Ken knew nothing about Steve’s existence and was innocent of the murders. Was Bianchi’s second personality a ruse, simply a way of disavowing responsibility for his actions? Indeed, Bianchi—a practiced liar who had read about multiple personality in psychology books—was later convicted.

Understanding Dissociative Identity Disorder

Skeptics question whether DID is a genuine disorder or an extension of our normal capacity for personality shifts. Nicholas Spanos (1986, 1994, 1996) asked college students to pretend they were accused murderers being examined by a psychiatrist. Given the same hypnotic treatment Bianchi received, most spontaneously expressed a second personality. This discovery made Spanos wonder: Are dissociative identities simply a more extreme version of our capacity to vary the “selves” we present—as when we display a goofy, loud self while hanging out with friends, and a subdued, respectful self around grandparents? Are clinicians who discover multiple personalities merely triggering role-playing by fantasy-prone people? Do these patients, like actors who commonly report “losing themselves” in their roles, then convince themselves of the authenticity of their own role enactments? Spanos was no stranger to this line of thinking. In a related research area, he had also raised these questions about the hypnotic state. Given that most DID patients are highly hypnotizable, whatever explains one condition—dissociation or role playing—may help explain the other.

Skeptics also find it suspicious that the disorder is so localized in time and space. Between 1930 and 1960, the number of DID diagnoses in North America was 2 per decade. In the 1980s, when the DSM contained the first formal code for this disorder, the number of reported cases had exploded to more than 20,000 (McHugh, 1995a). The average number of displayed personalities also mushroomed—from 3 to 12 per patient (Goff & Simms, 1993). Outside North America, the disorder is much less prevalent, although in other cultures some people are said to be “possessed” by an alien spirit (Aldridge-Morris, 1989; Kluff, 1991). In Britain, DID—which some have considered “a wacky American fad” (Cohen, 1995)—is rare. In India and Japan, it is essentially nonexistent (or at least unreported).

AP/Wide World Photos

The “Hillside Strangler” Kenneth Bianchi is shown here at his trial.

dissociative identity disorder (DID) a rare dissociative disorder in which a person exhibits two or more distinct and alternating personalities. Formerly called *multiple personality disorder*.

“Pretense may become reality.”

“Would it be possible to speak with the personality that pays the bills?”

“Though this be madness, yet there is method in ‘t.” -WILLIAM SHAKESPEARE, HAMLET, 1600

Such findings, skeptics say, point to a cultural phenomenon—a disorder created by therapists in a particular social context (Merskey, 1992). Rather than being provoked by trauma, dissociative symptoms tend to be exhibited by suggestible, fantasy-prone people (Giesbrecht et al., 2008, 2010). Patients do not enter therapy saying “Allow me to introduce myself.” Rather, note these skeptics, some therapists go fishing for multiple personalities: “Have you ever felt like another part of you does things you can’t control? Does this part of you have a name? Can I talk to the angry part of you?” Once patients permit a therapist to talk, by name, “to the part of you that says those angry things,” they begin acting out the fantasy. Like actors who lose themselves in their roles, vulnerable patients may “become” the parts they are acting out. The result may be the experience of another self.

Other researchers and clinicians believe DID is a real disorder. They find support for this view in the distinct brain and body states associated with differing personalities (Putnam, 1991). Handedness, for example, sometimes switches with personality (Henninger, 1992). Ophthalmologists have detected shifting visual acuity and eye-muscle balance as patients switched personalities, changes that did not occur among control group members trying to simulate DID (Miller et al., 1991). Dissociative disorder patients also have exhibited heightened activity in brain areas associated with the control and inhibition of traumatic memories (Elzinga et al., 2007).

Researchers and clinicians have interpreted DID symptoms from psychodynamic and learning perspectives. Both views agree that the symptoms are ways of dealing with anxiety. Psychodynamic theorists see them as defenses against the anxiety caused by the eruption of unacceptable impulses; a wanton second personality enables the discharge of forbidden impulses. Learning theorists see dissociative disorders as behaviors reinforced by anxiety reduction.

Other clinicians include dissociative disorders under the umbrella of posttraumatic stress disorder—a natural, protective response to “histories of childhood trauma” (Putnam, 1995; Spiegel, 2008). Many DID patients recall suffering physical, sexual, or emotional abuse as children (Gleaves, 1996; Lilienfeld et al., 1999). In one study of 12 murderers diagnosed with DID, 11 had suffered severe, torturous child abuse (Lewis et al., 1997). One was set afire by his parents. Another was used in child pornography and was scarred from being made to sit on a stove burner. Some critics wonder, however, whether vivid imagination or therapist suggestion contributes to such recollections (Kihlstrom, 2005).

So the debate continues. On one side are those who believe multiple personalities are the desperate efforts of the traumatized to detach from a horrific existence. On the other are the skeptics who think DID is a condition contrived by fantasy-prone, emotionally vulnerable people, and constructed out of the therapist-patient interaction. If the skeptics’ view wins, predicted psychiatrist Paul McHugh (1995b), “this epidemic will end in the way that the witch craze ended in Salem. The [multiple personality phenomenon] will be seen as manufactured.”

Before You Move On

▶ ASK YOURSELF

In a more normal way, do you ever flip between displays of different aspects of your personality?

▶ TEST YOURSELF

The psychodynamic and learning perspectives agree that dissociative identity disorder symptoms are ways of dealing with anxiety. How do their explanations differ?

Answers to the Test Yourself questions can be found in Appendix E at the end of the book.

Eating Disorders

69-3 How do anorexia nervosa, bulimia nervosa, and binge-eating disorder demonstrate the influence of psychological and genetic forces?

Our bodies are naturally disposed to maintain a steady weight, including stored energy reserves for times when food becomes unavailable. Yet sometimes psychological influences overwhelm biological wisdom. This becomes painfully clear in three eating disorders.

- **Anorexia nervosa** typically begins as a weight-loss diet. People with anorexia—usually adolescents and 9 times out of 10 females—drop significantly below normal weight. Yet they feel fat, fear being fat, and remain obsessed with losing weight, and sometimes exercise excessively. About half of those with anorexia display a binge-purge-depression cycle.
- **Bulimia nervosa** may also be triggered by a weight-loss diet, broken by gorging on forbidden foods. Binge-purge eaters—mostly women in their late teens or early twenties—eat in spurts, sometimes influenced by friends who are bingeing (Crandall, 1988). In a cycle of repeating episodes, overeating is followed by compensatory purging (through vomiting or laxative use), fasting, or excessive exercise (Wonderlich et al., 2007). Preoccupied with food (craving sweet and high-fat foods), and fearful of becoming overweight, binge-purge eaters experience bouts of depression and anxiety during and following binges (Hinz & Williamson, 1987; Johnson et al., 2002). Unlike anorexia, bulimia is marked by weight fluctuations within or above normal ranges, making the condition easy to hide.
- Those who do significant binge eating, followed by remorse—but do not purge, fast, or exercise excessively—are said to have **binge-eating disorder**.

A national study funded by the U.S. National Institute of Mental Health reported that, at some point during their lifetime, 0.6 percent of people meet the criteria for anorexia, 1 percent for bulimia, and 2.8 percent for binge-eating disorder (Hudson et al., 2007). So, how can we explain these disorders?

Eating disorders do *not* provide (as some have speculated) a telltale sign of childhood sexual abuse (Smolak & Murnen, 2002; Stice, 2002). The family environment may provide a fertile ground for the growth of eating disorders in other ways, however.

- Mothers of girls with eating disorders tend to focus on their own weight and on their daughters' weight and appearance (Pike & Rodin, 1991).
- Families of bulimia patients have a higher-than-usual incidence of childhood obesity and negative self-evaluation (Jacobi et al., 2004).
- Families of anorexia patients tend to be competitive, high-achieving, and protective (Pate et al., 1992; Yates, 1989, 1990).

Those with eating disorders often have low self-evaluations, set perfectionist standards, fret about falling short of expectations, and are intensely concerned with how others perceive them (Pieters et al., 2007; Polivy & Herman, 2002; Sherry & Hall, 2009). Some of these factors also predict teen boys' pursuit of unrealistic muscularity (Ricciardelli & McCabe, 2004).

Genetics also influence susceptibility to eating disorders. Twins are more likely to share the disorder if they are identical rather than fraternal (Culbert et al., 2009; Klump et al., 2009; Root et al., 2010). Scientists are now searching for culprit genes, which may influence the body's available serotonin and estrogen (Klump & Culbert, 2007).

But these disorders also have cultural and gender components. Ideal shapes vary across culture and time. In impoverished areas of the world, including much of Africa—where plumpness means prosperity and thinness can signal poverty or illness—bigger

Jeff Kowitz/FilmMagic for MTV/Getty Images

Dying to be thin Anorexia was identified and named in the 1870s, when it appeared among affluent adolescent girls (Brumberg, 2000). Many modern-day celebrities, including Lady Gaga, have struggled publicly with eating disorders.

anorexia nervosa an eating disorder in which a person (usually an adolescent female) maintains a starvation diet despite being significantly (15 percent or more) underweight.

bulimia nervosa an eating disorder in which a person alternates binge eating (usually of high-calorie foods) with purging (by vomiting or laxative use), excessive exercise, or fasting.

binge-eating disorder significant binge-eating episodes, followed by distress, disgust, or guilt, but without the compensatory purging or fasting that marks bulimia nervosa.

“Gee, I had no idea you were married to a supermodel.”

“Skeletons on Parade” A newspaper article used this headline in criticizing the display of superthin models. Do such models make self-starvation fashionable?

“Why do women have such low self-esteem? There are many complex psychological and societal reasons, by which I mean Barbie.” -DAVE BARRY, 1999

WireImage/Getty Images

seems better (Knickmeyer, 2001; Swami et al., 2010). Bigger does not seem better in Western cultures, where, according to 222 studies of 141,000 people, the rise in eating disorders over the last 50 years has coincided with a dramatic increase in women having a poor body image (Feingold & Mazzella, 1998).

Those most vulnerable to eating disorders are also those (usually women or gay men) who most idealize thinness and have the greatest body dissatisfaction (Feldman & Meyer, 2010; Kane, 2010; Stice et al., 2010). Should it surprise us, then, that when women view real and doctored images of unnaturally thin models and celebrities, they often feel ashamed, depressed, and dissatisfied with their own bodies—the very attitudes that predispose eating disorders (Grabe et al., 2008; Myers & Crowther, 2009; Tiggemann & Miller, 2010)? Researchers tested this modeling idea by giving some adolescent girls (but not others) a 15-month subscription to an American teen-fashion magazine (Stice et al., 2001). Compared with

their counterparts who had not received the magazine, vulnerable girls—defined as those who were already dissatisfied, idealizing thinness, and lacking social support—exhibited increased body dissatisfaction and eating disorder tendencies. But even ultra-thin models do not reflect the impossible standard of the classic Barbie doll, who had, when adjusted to a height of 5 feet 7 inches, a 32–16–29 figure (in centimeters, 82–41–73) (Norton et al., 1996).

It seems clear that the sickness of today’s eating disorders lies in part within our weight-obsessed culture—a culture that says, in countless ways, “Fat is bad,” that motivates millions of women to be “always dieting,” and that encourages eating binges by pressuring women to live in a constant state of semistarvation. If cultural learning contributes to eating behavior, then might prevention programs increase acceptance of one’s body? Reviews of prevention studies answer *Yes*, and especially if the programs are interactive and focused on girls over age 15 (Stice et al., 2007; Vocks et al., 2010).

Personality Disorders

69-4

What are the three clusters of personality disorders? What behaviors and brain activity characterize the antisocial personality?

Some dysfunctional behavior patterns impair people’s social functioning without depression or delusions. Among them are **personality disorders**—disruptive, inflexible, and enduring behavior patterns that impair one’s social functioning. Anxiety is a feature of one cluster of these disorders, such as a fearful sensitivity to rejection that predisposes the withdrawn *avoidant personality disorder*. A second cluster expresses eccentric or odd behaviors, such as the emotionless disengagement of the *schizoid personality disorder*. A third cluster exhibits dramatic or impulsive behaviors, such as the attention-getting *histrionic personality disorder* and the self-focused and self-inflating *narcissistic personality disorder*.

personality disorders

psychological disorders characterized by inflexible and enduring behavior patterns that impair social functioning.

EPA/JEFF TUTTLE/Landov

No remorse Dennis Rader, known as the “BTK killer” in Kansas, was convicted in 2005 of killing 10 people over a 30-year span. Rader exhibited the extreme lack of conscience that marks antisocial personality disorder.

AP® Exam Tip

Notice how different antisocial personality disorder is from the other disorders you have studied in this unit. Because individuals with antisocial personality disorder so often behave badly, they tend to be viewed differently from people with disorders such as depression or phobia.

Antisocial Personality Disorder

The most troubling and heavily researched personality disorder is the **antisocial personality disorder**. The person (sometimes called a *sociopath* or a *psychopath*) is typically a male whose lack of conscience becomes plain before age 15, as he begins to lie, steal, fight, or display unrestrained sexual behavior (Cale & Lilienfeld, 2002). About half of such children become antisocial adults—unable to keep a job, irresponsible as a spouse and parent, and assaultive or otherwise criminal (Farrington, 1991). When the antisocial personality combines a keen intelligence with amorality, the result may be a charming and clever con artist, a ruthless corporate executive (*Snakes in Suits* is a book on antisocial behavior in business)—or worse.

Despite their remorseless and sometimes criminal behavior, criminality is not an essential component of antisocial behavior (Skeem & Cooke, 2010). Moreover, many criminals do not fit the description of antisocial personality disorder. Why? Because they actually show responsible concern for their friends and family members.

Antisocial personalities behave impulsively, and then feel and fear little (Fowles & Dindo, 2009). The results sometimes are horrifying, as they were in the case of Henry Lee Lucas. He killed his first victim when he was 13. He felt little regret then or later. He confessed that, during his 32 years of crime, he had brutally beaten, suffocated, stabbed, shot, or mutilated some 360 women, men, and children. For the last 6 years of his reign of terror, Lucas teamed with Elwood Toole, who reportedly slaughtered about 50 people he “didn’t think was worth living anyhow” (Darrach & Norris, 1984).

Understanding Antisocial Personality Disorder

Antisocial personality disorder is woven of both biological and psychological strands. No single gene codes for a complex behavior such as crime, but twin and adoption studies reveal that biological relatives of those with antisocial and unemotional tendencies are at increased risk for antisocial behavior (Larsson et al., 2007; Livesley & Jang, 2008). Molecular geneticists have identified some specific genes that are more common in those with antisocial personality disorder (Gunter et al., 2010). The genetic vulnerability of people

“Thursday is out. I have jury duty.”

Many criminals, like this one, exhibit a sense of conscience and responsibility in other areas of their life, and thus do not exhibit antisocial personality disorder.

antisocial personality disorder

a personality disorder in which a person (usually a man) exhibits a lack of conscience for wrongdoing, even toward friends and family members. May be aggressive and ruthless or a clever con artist.

Figure 69.1

Cold-blooded arousability and risk of crime

Levels of the stress hormone adrenaline were measured in two groups of 13-year-old Swedish boys. In both stressful and nonstressful situations, those who would later be convicted of a crime as 18- to 26-year-olds showed relatively low arousal. (From Magnusson, 1990.)

with antisocial and unemotional tendencies appears as a fearless approach to life. Awaiting aversive events, such as electric shocks or loud noises, they show little autonomic nervous system arousal (Hare, 1975; van Goozen et al., 2007). Long-term studies have shown that their levels of stress hormones were lower than average when they were youngsters, before committing any crime (**FIGURE 69.1**). Three-year-olds who are slow to develop conditioned fears are later more likely to commit a crime (Gao et al., 2010).

Other studies have found that preschool boys who later became aggressive or antisocial adolescents tended to be impulsive, uninhibited, unconcerned with social rewards, and low in anxiety (Caspi et al., 1996; Tremblay et al., 1994). If channeled in more productive directions, such fearlessness may lead to courageous heroism, adventurism, or star-level athleticism (Poulton & Milne, 2002). Lacking a sense of social responsibility, the same disposition may produce a cool con artist or killer (Lykken, 1995). The genes that put people at risk for antisocial behavior also put people at risk for substance use disorders, which helps explain why

these disorders often appear in combination (Dick, 2007).

Genetic influences, often in combination with child abuse, help wire the brain (Dodge, 2009). Adrian Raine (1999, 2005) compared PET scans of 41 murderers' brains with those from people of similar age and sex. Raine found reduced activity in the murderers' frontal lobes, an area of the cortex that helps control impulses (**FIGURE 69.2**). This reduction was especially apparent in those who murdered impulsively. In a follow-up study, Raine and his team (2000) found that violent repeat offenders had 11 percent less frontal lobe tissue than normal. This helps explain why people with antisocial personality disorder exhibit marked deficits in frontal lobe cognitive functions, such as planning, organization, and inhibition (Morgan & Lilienfeld, 2000). Compared with people who feel and display empathy, their brains also respond less to facial displays of others' distress (Deeley et al., 2006).

A biologically based fearlessness, as well as early environment, helps explain the reunion of long-separated sisters Joyce Lott, 27, and Mary Jones, 29—in a South Carolina prison where both were sent on drug charges. After a newspaper story about their reunion, their long-lost half-brother Frank Strickland called. He explained it would be a while before he could come see them—because he, too, was in jail, on drug, burglary, and larceny charges (Shepherd et al., 1990).

Genetics alone is hardly the whole story of antisocial crime, however. A study of criminal tendencies among young Danish men illustrates the usefulness of a complete biopsychosocial approach. Another Adrian Raine-led study (1996) checked criminal records on nearly 400 men at ages 20 to 22, knowing that these men either had experienced biological risk factors at birth (such as premature birth) or came from family backgrounds marked by

FYI

Does a full Moon trigger "madness" in some people? James Rotton and I. W. Kelly (1985) examined data from 37 studies that related lunar phase to crime, homicides, crisis calls, and mental hospital admissions. Their conclusion: There is virtually no evidence of "Moon madness." Nor does lunar phase correlate with suicides, assaults, emergency room visits, or traffic disasters (Martin et al., 1992; Raison et al., 1999).

Figure 69.2

Murderous minds Researchers have found reduced activation in a murderer's frontal lobes. This brain area (shown in a left-facing brain) helps brake impulsive, aggressive behavior (Raine, 1999).

poverty and family instability. The researchers then compared each of these two groups with a third *biosocial* group whose lives were marked by *both* the biological and social risk factors. The biosocial group had double the risk of committing a crime (**FIGURE 69.3**). Similar findings emerged from a famous study that followed 1037 children for a quarter-century: Two combined factors—childhood maltreatment and a gene that altered neurotransmitter balance—predicted antisocial problems (Caspi et al., 2002). Neither “bad” genes alone nor a “bad” environment alone predisposed later antisocial behavior. Rather, genes predisposed some children to be more sensitive to maltreatment. Within “genetically vulnerable segments of the population,” environmental influences matter—for better or for worse (Belsky et al., 2007; Moffitt, 2005).

With antisocial behavior, as with so much else, nature and nurture interact and together leave their marks on the brain. To explore the neural basis of antisocial behavior, neuroscientists are identifying brain activity differences in criminals who display antisocial personality disorder. Shown emotionally evocative photographs, such as a man holding a knife to a woman’s throat, they display lower heart rate and perspiration responses, and less activity in brain areas that typically respond to emotional stimuli (Harenski et al., 2010; Kiehl & Buckholtz, 2010). They also display a hyper-reactive dopamine reward system that predisposes their impulsive drive to do something rewarding, despite the consequences (Buckholtz et al., 2010). Such data provide another reminder: Everything psychological is also biological.

Before You Move On

▶ ASK YOURSELF

Given what we have learned in earlier units about the powers and limits of parental influence, how much do you think parental training might affect the risk of a child’s developing antisocial personality disorder?

▶ TEST YOURSELF

What contribution do genes make to the development of antisocial personality disorder?

Answers to the Test Yourself questions can be found in Appendix E at the end of the book.

Module 69 Review

69-1 What are somatic symptom and related disorders?

- *Somatic symptom disorder* presents a somatic (bodily) symptom—some physiologically unexplained but genuinely felt ailment.
- With *conversion disorder* (also called functional neurological symptom disorder), anxiety appears converted to a physical symptom that has no reasonable neurological basis.
- The more common *illness anxiety disorder* is the interpretation of normal sensations as a dreaded disorder.

69-2 What are dissociative disorders, and why are they controversial?

- *Dissociative disorders* are conditions in which conscious awareness seems to become separated from previous memories, thoughts, and feelings.
- Skeptics note that *dissociative identity disorder*, formerly known as multiple personality disorder, increased dramatically in the late twentieth century, that it is rarely found outside North America, and that it may reflect role-playing by people who are vulnerable to therapists' suggestions. Others view this disorder as a manifestation of feelings of anxiety, or as a response learned when behaviors are reinforced by anxiety-reduction.

69-3 How do anorexia nervosa, bulimia nervosa, and binge-eating disorder demonstrate the influence of psychological and genetic forces?

- In these eating disorders, psychological factors may overwhelm the homeostatic drive to maintain a balanced internal state.
- Despite being significantly underweight, people with *anorexia nervosa* (usually adolescent females) continue to diet because they view themselves as fat.
- Those with *bulimia nervosa* (usually females in their teens and twenties) secretly binge and then compensate by purging, fasting, or excessively exercising.
- Those with *binge-eating disorder* binge but do not follow bingeing with purging, fasting, or exercise.
- Cultural pressures, low self-esteem, and negative emotions interact with stressful life experiences and genetics to produce eating disorders.

69-4 What are the three clusters of personality disorders? What behaviors and brain activity characterize the antisocial personality?

- *Personality disorders* are disruptive, inflexible, and enduring behavior patterns that impair social functioning.
- These disorders form clusters, based on three main characteristics: (1) anxiety; (2) eccentric or odd behaviors; and (3) dramatic or impulsive behaviors.
- *Antisocial personality disorder* is characterized by a lack of conscience and, sometimes, by aggressive and fearless behavior. Genetic predispositions may interact with the environment to produce the altered brain activity associated with antisocial personality disorder.

Multiple-Choice Questions

1. Adela regularly interprets ordinary physical symptoms like stomach cramps and headaches as serious medical problems. Her doctor is unable to convince her that her problems are not serious. Adela suffers from
 - a. illness anxiety disorder.
 - b. conversion disorder.
 - c. fugue state.
 - d. dissociative identity disorder.
 - e. anorexia nervosa.
2. Which of the following is the diagnosis given to people with multiple personalities?
 - a. Schizophrenia
 - b. Antisocial personality disorder
 - c. Fugue state
 - d. Conversion disorder
 - e. Dissociative identity disorder

3. Which of the following is the defining characteristic of antisocial personality disorder?
- Violence
 - Lack of conscience
 - Mood swings
 - Unexplained physical symptoms
 - Committing serial murders

Practice FRQs

1. Name and briefly describe three eating disorders.

Answer

1 point: Anorexia nervosa is a disorder in which the individuals starve themselves despite being significantly underweight.

1 point: Bulimia nervosa is a disorder in which the individual alternates between bingeing and purging.

1 point: Binge-eating disorder is a disorder in which the individual binges without purging.

2. Dissociative identity disorder (DID) is among the most controversial of all psychological disorders. Briefly describe the disorder. Then, provide one piece of evidence that supports the existence of the disorder and one piece of evidence that would indicate the disorder might not be genuine.

AP[®] Exam Practice Questions

Multiple-Choice Questions

- Which of the following statements is *false*?
 - Many behavioral and cognitive changes accompany depression.
 - Someone suffering from depression will get better only with therapy or medication.
 - Compared with men, women are nearly twice as vulnerable to major depression.
 - Stressful events related to work, marriage, and close relationships often precede depression.
 - With each new generation, depression is striking earlier and affecting more people.
- The risk of major depression and bipolar disorder dramatically increases if you
 - have suffered a debilitating injury.
 - have an adoptive parent that has the disorder.
 - have a parent or sibling with the disorder.
 - have a life-threatening illness.
 - have above-average intelligence.
- What do mental health professionals call a clinically significant disturbance in an individual's cognition, emotion regulation, or behavior?
 - An interaction of nature and nurture
 - A physiological state
 - A genetic predisposition
 - A psychological factor
 - A psychological disorder
- Adolescent mood swings might be misdiagnosed as which psychological disorder?
 - Schizophrenia
 - Temper tantrums
 - Oppositional defiant disorder
 - Bipolar disorder
 - ADHD
- A split from reality that shows itself in disorganized thinking, disturbed perceptions, and/or diminished or inappropriate emotions is associated with which psychological disorder?
 - Schizophrenia
 - Phobias
 - Depression
 - Bipolar disorder
 - Anxiety

- 6.** The nearly 1-in-100 odds of any person being diagnosed with schizophrenia become about 1 in 10 among those
- who also suffer anxiety disorder.
 - whose sibling or parent has the disorder.
 - who have been diagnosed with depression.
 - who live with someone diagnosed with schizophrenia.
 - whose identical twin has schizophrenia.
- 7.** Which of the following can be characterized as a compulsion?
- Worry about exposure to germs or toxins
 - Fear that something terrible is about to happen
 - Concern with making sure things are in symmetrical order
 - Anxiety when objects are not lined up in an exact pattern
 - Checking repeatedly to see if doors are locked
- 8.** Sensory experiences without sensory stimulation are called
- word salads.
 - delusions.
 - paranoid thoughts.
 - ruminations.
 - hallucinations.
- 9.** What is the most common reason people seek mental health services?
- Depression
 - Bipolar disorder
 - Posttraumatic stress disorder
 - Dissociative identity disorder
 - Illness anxiety disorder
- 10.** Brain-scanning techniques reveal what kinds of brain activity differences in people with chronic schizophrenia?
- Abnormally high brain activity in the frontal lobes
 - An increase in the brain waves that reflect synchronized neural firing
 - Abnormal activity in multiple brain areas
 - Decreased activity in the amygdala
 - A lack of dopamine receptors
- 11.** Which personality disorder is associated with a lack of regret over violating others' rights?
- Antisocial personality disorder
 - Avoidant personality disorder
 - Schizoid personality disorder
 - Histrionic personality disorder
 - Narcissistic personality disorder
- 12.** What term refers to thoughts about who or what we blame for our successes and failures?
- Stability
 - Emotional memory
 - The social-cognitive perspective
 - Explanatory style
 - Dissociative reasoning
- 13.** Although some psychological disorders are culture-bound, others are universal. Which of the following disorders is found in every known culture?
- Bulimia nervosa
 - Anorexia nervosa
 - Susto
 - Schizophrenia
 - Taijin-kyofusho
- 14.** Modern psychologists contend that all behavior, whether it is called normal or disordered, arises from the interaction of
- genetics and physiology.
 - children and parents.
 - experience and wisdom.
 - inborn tendencies and drives.
 - nature and nurture.
- 15.** Which of the following are symptoms of generalized anxiety disorder?
- Unexplainable and continual tension
 - Sudden episodes of intense dread
 - Irrational and intense fear of a specific object or situation
 - Repetitive thoughts or actions
 - Nightmares for weeks after a severe, uncontrollable event

Free-Response Questions

- After reading her AP[®] Psychology text, Jane starts to wonder if all young people have some kind of psychological disorder. First, briefly explain what you might say to Jane about the criteria psychologists use when diagnosing mental illnesses. Then, briefly explain the symptoms associated with the following diagnoses and how age might be related to each diagnosis:
 - ADHD
 - Anorexia nervosa
 - OCD
 - Bipolar disorder

Rubric for Free-Response Question 1

1 point: Psychologists define a disorder as a significant disturbance in thinking, emotion, and/or behavior that is maladaptive. Jane's general statement that all young people have a psychological disorder doesn't make sense in this context: It's not likely that all young people have significant disturbances that interfere with their day-to-day lives.

🔗 page 651

1 point: ADHD: The symptoms of ADHD involve inattention, hyperactivity, and impulsivity. ADHD is diagnosed more often in young people, but some adults are also diagnosed with ADHD. 🔗 page 652

1 point: Anorexia nervosa: The symptoms of anorexia nervosa involve a starvation diet that results in a person weighing at least 15 percent less than he or she should. Often the symptoms of anorexia nervosa appear in adolescence since body image is likely to be a focus during this time of life, but people of any age might suffer from this disorder.

🔗 page 697

1 point: OCD: The symptoms of OCD involve unwanted repetitive thoughts (obsessions) and actions (compulsions). This disorder is more commonly diagnosed in teens and young adults. 🔗 pages 663–664

1 point: Bipolar disorder: The symptoms of bipolar disorder involve alternating between mania and depression. Some psychologists think that adolescent mood swings might have caused the increase in this diagnosis among young people in recent years. 🔗 pages 673–674

- Describe what the terms *obsession* and *compulsion* refer to in the context of obsessive-compulsive disorder. Then, briefly explain

- an example of a common obsession experienced by individuals with obsessive-compulsive disorder.
- an example of a common compulsion experienced by individuals with obsessive-compulsive disorder.
- how the learning perspective explains compulsions.
- how the biological perspective explains compulsions.

(6 points)

- Psychologists organize psychological disorders into categories (in publications such as the DSM-5) in order to communicate commonalities and differences among psychological disorders, and to imply appropriate treatment and encourage future research. For each of the psychological disorders below, explain what psychological disorder category it should be organized into, and why it "belongs" in that category.

- Major depressive disorder
- Dissociative identity disorder
- Panic disorder
- Phobias

(4 points)

Unit XIII

Treatment of Abnormal Behavior

Modules

- 70** Introduction to Therapy, and Psychodynamic and Humanistic Therapies
- 71** Behavior, Cognitive, and Group Therapies
- 72** Evaluating Psychotherapies and Prevention Strategies
- 73** The Biomedical Therapies

Kay Redfield Jamison, an award-winning clinical psychologist and world expert on the emotional extremes of bipolar disorder, knows her subject first-hand. “For as long as I can remember,” she recalled in *An Unquiet Mind*, “I was frighteningly, although often wonderfully, beholden to moods. Intensely emotional as a child, mercurial as a young girl, first severely depressed as an adolescent, and then unrelentingly caught up in the cycles of manic-depressive illness [now known as bipolar disorder] by the time I began my professional life, I became, both by necessity and intellectual inclination, a student of moods” (1995, pp. 4–5). Her life was blessed with times of intense sensitivity and passionate energy. But like her father’s, it was also at times plagued by reckless spending, racing conversation, and sleeplessness, alternating with swings into “the blackest caves of the mind.”

Then, “in the midst of utter confusion,” she made a sane and profoundly helpful decision. Risking professional embarrassment she made an appointment with a therapist, a psychiatrist she would visit weekly for years to come.

He kept me alive a thousand times over. He saw me through madness, despair, wonderful and terrible love affairs, disillusionments and triumphs, recurrences of illness, an almost fatal suicide attempt, the death of a man I greatly loved, and the enormous pleasures and aggravations of my professional life. . . . He was very tough, as well

as very kind, and even though he understood more than anyone how much I felt I was losing—in energy, vivacity, and originality—by taking medication, he never was seduced into losing sight of the overall perspective of how costly, damaging, and life threatening my illness was. . . . Although I went to him to be treated for an illness, he taught me . . . the total beholdenness of brain to mind and mind to brain (pp. 87–88).

“Psychotherapy heals,” Jamison reports. “It makes some sense of the confusion, reins in the terrifying thoughts and feelings, returns some control and hope and possibility from it all.”

Module 70

Introduction to Therapy, and Psychodynamic and Humanistic Therapies

Module Learning Objectives

70-1

Discuss how *psychotherapy*, *biomedical therapy*, and an *eclectic approach* to therapy differ.

70-2

Discuss the goals and techniques of psychoanalysis, and describe how they have been adapted in psychodynamic therapy.

70-3

Identify the basic themes of humanistic therapy, and describe the specific goals and techniques of Rogers' client-centered approach.

Image Source RF/Sydney Bourne/Getty Images

The long history of efforts to treat psychological disorders has included a bewildering mix of harsh and gentle methods. Well-meaning individuals have cut holes in people's heads and restrained, bled, or “beat the devil” out of them. But they also have given warm baths and massages and placed people in sunny, serene environments. They have administered drugs and electric shocks. And they have talked with their patients about childhood experiences, current feelings, and maladaptive thoughts and behaviors.

Reformers Philippe Pinel and Dorothea Dix pushed for gentler, more humane treatments and for constructing mental hospitals. Since the 1950s, the introduction of effective drug therapies and community-based treatment programs have emptied most of those hospitals.

Introduction to Therapy

70-1 How do *psychotherapy*, *biomedical therapy*, and an *eclectic approach* to therapy differ?

Today’s therapies can be classified into two main categories. In **psychotherapy**, a trained therapist uses psychological techniques to assist someone seeking to overcome difficulties or achieve personal growth. **Biomedical therapy** offers medication or other biological treatments.

Many therapists combine techniques. Jamison received psychotherapy in her meetings with her psychiatrist, and she took medications to control her wild mood swings. Many psychotherapists describe themselves as taking an **eclectic approach**, using a blend of psychotherapies. Like Jamison, many patients also can receive psychotherapy combined with medication.

Let’s look first at the psychotherapeutic “talk therapies.” Among the dozens of types of psychotherapy, we will look at the most influential. Each is built on one or more of psychology’s major theories: psychodynamic, humanistic, behavioral, and cognitive. Most of these techniques can be used one-on-one or in groups. We’ll explore psychodynamic and humanistic therapies in this module, and behavior, cognitive, and group therapies in Module 71.

The history of treatment Visitors to eighteenth-century mental hospitals paid to gawk at patients, as though they were viewing zoo animals. William Hogarth’s (1697–1764) painting captured one of these visits to London’s St. Mary of Bethlehem hospital (commonly called Bedlam).

AP® Exam Tip

Most of the treatments discussed in this unit come from the perspectives you’ve been learning about since Unit I. As you reach each major section—like the upcoming one on psychoanalytic and psychodynamic therapy—try to anticipate how someone from that perspective would approach therapy (for example, “What would Freud do?”). This should help you organize and retain the information as you read.

Psychoanalysis and Psychodynamic Therapy

70-2 What are the goals and techniques of psychoanalysis, and how have they been adapted in psychodynamic therapy?

Sigmund Freud’s **psychoanalysis** was the first of the psychological therapies. Few clinicians today practice therapy as Freud did, but his work deserves discussion as part of the foundation for treating psychological disorders.

Goals

Psychoanalytic theory presumes that healthier, less anxious living becomes possible when people release the energy they had previously devoted to id-ego-superego conflicts (see Module 55). Freud assumed that we do not fully know ourselves. There are threatening things that we seem to want not to know—that we disavow or deny. “We can have loving feelings and hateful feelings toward the same person,” notes Jonathan Shedler (2009), and “we can desire something and also fear it.”

psychotherapy treatment involving psychological techniques; consists of interactions between a trained therapist and someone seeking to overcome psychological difficulties or achieve personal growth.

biomedical therapy prescribed medications or procedures that act directly on the person’s physiology.

eclectic approach an approach to psychotherapy that, depending on the client’s problems, uses techniques from various forms of therapy.

psychoanalysis Sigmund Freud’s therapeutic technique. Freud believed the patient’s free associations, resistances, dreams, and transferences—and the therapist’s interpretations of them—released previously repressed feelings, allowing the patient to gain self-insight.

Freud's therapy aimed to bring patients' repressed or disowned feelings into conscious awareness. By helping them reclaim their unconscious thoughts and feelings and giving them *insight* into the origins of their disorders, he aimed to help them reduce growth-impeding inner conflicts.

"I'm more interested in hearing about the eggs you're hiding from yourself."

AP® Exam Tip

Psychoanalytic treatment is the public image of psychology. If you were to ask people to sketch a psychologist at work, you would see lots of sketches of therapists taking notes while they were seated behind patients on couches. Keep in mind that most modern therapy is very different from this image, and psychology careers stretch well beyond therapy.

"I haven't seen my analyst in 200 years. He was a strict Freudian. If I'd been going all this time, I'd probably almost be cured by now." -WOODY ALLEN, AFTER AWAKENING FROM SUSPENDED ANIMATION IN THE MOVIE *SLEEPER*

resistance in psychoanalysis, the blocking from consciousness of anxiety-laden material.

interpretation in psychoanalysis, the analyst's noting supposed dream meanings, resistances, and other significant behaviors and events in order to promote insight.

transference in psychoanalysis, the patient's transfer to the analyst of emotions linked with other relationships (such as love or hatred for a parent).

psychodynamic therapy therapy deriving from the psychoanalytic tradition that views individuals as responding to unconscious forces and childhood experiences, and that seeks to enhance self-insight.

Techniques

Psychoanalysis is historical reconstruction. Psychoanalytic theory emphasizes the formative power of childhood experiences and their ability to mold the adult. Thus, it aims to unearth one's past in hope of unmasking the present. After discarding hypnosis as an unreliable excavator, Freud turned to *free association*.

Imagine yourself as a patient using free association. First, you relax, perhaps by lying on a couch. As the psychoanalyst sits out of your line of vision, you say aloud whatever comes to mind. At one moment, you're relating a childhood memory. At another, you're describing a dream or recent experience. It sounds easy, but soon you notice how often you edit your thoughts as you speak. You pause for a second before uttering an embarrassing thought. You omit what seems trivial, irrelevant, or shameful. Sometimes your mind goes blank or you find yourself unable to remember important details. You may joke or change the subject to something less threatening.

To the analyst, these mental blocks indicate **resistance**. They hint that anxiety lurks and you are defending against sensitive material. The analyst will note your resistances and then provide insight into their meaning. If offered at the right moment, this **interpretation**—of, say, your not wanting to talk about your mother—may illuminate the underlying wishes, feelings, and conflicts you are avoiding. The analyst may also offer an explanation of how this resistance fits with other pieces of your psychological puzzle, including those based on analysis of your dream content.

Over many such sessions, your relationship patterns surface in your interaction with your therapist. You may find yourself experiencing strong positive or negative feelings for your analyst. The analyst may suggest you are **transferring** feelings, such as dependency or mingled love and anger, that you experienced in earlier relationships with family members or other important people. By exposing such feelings, you may gain insight into your current relationships.

Relatively few U.S. therapists now offer traditional psychoanalysis. Much of its underlying theory is not supported by scientific research (Module 56). Analysts' interpretations cannot be proven or disproven. And psychoanalysis takes considerable time and money, often years of several sessions per week. Some of these problems have been addressed in the modern psychodynamic perspective that has evolved from psychoanalysis.

Psychodynamic Therapy

Therapists who use **psychodynamic therapy** techniques don't talk much about id, ego, and superego. Instead they try to help people understand their current symptoms. They focus on themes across important relationships, including childhood experiences and the therapist relationship. Rather than lying on a couch, out of the therapist's line of vision, patients meet with their therapist face to face. These meetings take place once or twice a week (rather than several times per week), and often for only a few weeks or months (rather than several years).

In these meetings, patients explore and gain perspective into defended-against thoughts and feelings. Therapist David Shapiro (1999, p. 8) illustrates with the case of a young man who had told women that he loved them, when knowing well that he didn't. They expected it, so he said it. But later with his wife, who wishes he would say that he loves her, he finds he "cannot" do that—"I don't know why, but I can't."

Therapist: Do you mean, then, that if you could, you would like to?

Patient: Well, I don't know. . . . Maybe I can't say it because I'm not sure it's true. Maybe I don't love her.

Further interactions reveal that he can't express real love because it would feel "mushy" and "soft" and therefore unmanly. He is "in conflict with himself, and he is cut off from the nature of that conflict." Shapiro noted that with such patients, who are estranged from themselves, therapists using psychodynamic techniques "are in a position to introduce them to themselves. We can restore their awareness of their own wishes and feelings, and their awareness, as well, of their reactions against those wishes and feelings."

Psychodynamic therapies may also help reveal past relationship troubles as the origin of current difficulties. Jonathan Shedler (2010a) recalls his patient Jeffrey's complaints of difficulty getting along with his colleagues and wife, who saw him as hypercritical. Jeffrey then "began responding to me as if I were an unpredictable, angry adversary." Shedler seized this opportunity to help Jeffrey recognize the relationship pattern, and its roots in the attacks and humiliation he experienced from his alcohol-abusing father—and to work through and let go of this defensive responding to people.

Interpersonal psychotherapy, a brief (12- to 16-session) variation of psychodynamic therapy, has effectively treated depression (Cuijpers, 2011). Although interpersonal psychotherapy aims to help people gain insight into the roots of their difficulties, its goal is symptom relief in the here and now. Rather than focusing mostly on undoing past hurts and offering interpretations, the therapist concentrates primarily on current relationships and on helping people improve their relationship skills.

The case of Anna, a 34-year-old married professional, illustrates these goals. Five months after receiving a promotion, with accompanying increased responsibilities and longer hours, Anna experienced tensions with her husband over his wish for a second child. She began feeling depressed, had trouble sleeping, became irritable, and was gaining weight. A therapist using psychodynamic techniques might have helped Anna gain insight into her angry impulses and her defenses against anger. A therapist applying interpersonal techniques would concur but would also engage her thinking on more immediate issues—how she could balance work and home, resolve the dispute with her husband, and express her emotions more effectively (Markowitz et al., 1998).

Humanistic Therapies

70-3 What are the basic themes of humanistic therapy? What are the specific goals and techniques of Rogers' client-centered approach?

The humanistic perspective (Module 57) has emphasized people's inherent potential for self-fulfillment. Like psychodynamic therapies, humanistic therapies have attempted to reduce growth-impeding inner conflicts by providing clients with new insights. Indeed, the psychodynamic and humanistic therapies are often referred to as **insight therapies**. But humanistic therapy differs from psychoanalytic therapy in many other ways:

- *Humanistic therapy aims to boost people's self-fulfillment by helping them grow in self-awareness and self-acceptance.*
- *Promoting this growth, not curing illness, is the focus of therapy.* Thus, those in therapy became "clients" or just "persons" rather than "patients" (a change many other therapists have adopted).
- *The path to growth is taking immediate responsibility for one's feelings and actions, rather than uncovering hidden determinants.*
- *Conscious thoughts are more important than the unconscious.*
- *The present and future are more important than the past.* The goal is to explore feelings as they occur, rather than achieve insights into the childhood origins of the feelings.

Veronique Burger/Science Source

Face-to-face therapy

In contemporary psychodynamic therapy, the couch has disappeared. But the influence of psychoanalytic theory continues in some areas, as the therapist seeks information from the patient's childhood and helps the person bring unconscious feelings into conscious awareness.

insight therapies a variety of therapies that aim to improve psychological functioning by increasing a person's awareness of underlying motives and defenses.

AP® Exam Tip

You can remember Acceptance, Genuineness, and Empathy as “AGE.”

“We have two ears and one mouth that we may listen the more and talk the less.” -ZENO, 335–263 B.C.E., *DIODEGENES LAERTIUS*

Carl Rogers (1902–1987) developed the widely used humanistic technique he called **client-centered therapy**, which focuses on the person’s conscious self-perceptions. In this *nondirective therapy*, the therapist listens, without judging or interpreting, and seeks to refrain from directing the client toward certain insights.

Believing that most people possess the resources for growth, Rogers (1961, 1980) encouraged therapists to exhibit *acceptance*, *genuineness*, and *empathy*. When therapists enable their clients to feel unconditionally accepted, when they drop their façades and genuinely express their true feelings, and when they empathically sense and reflect their clients’ feelings, the clients may deepen their self-understanding and self-acceptance (Hill & Nakayama, 2000). As Rogers (1980, p. 10) explained,

Hearing has consequences. When I truly hear a person and the meanings that are important to him at that moment, hearing not simply his words, but him, and when I let him know that I have heard his own private personal meanings, many things happen. There is first of all a grateful look. He feels released. He wants to tell me more about his world. He surges forth in a new sense of freedom. He becomes more open to the process of change.

I have often noticed that the more deeply I hear the meanings of the person, the more there is that happens. Almost always, when a person realizes he has been deeply heard, his eyes moisten. I think in some real sense he is weeping for joy. It is as though he were saying, “Thank God, somebody heard me. Someone knows what it’s like to be me.”

“Hearing” refers to Rogers’ technique of **active listening**—echoing, restating, and seeking clarification of what the person expresses (verbally or nonverbally) and acknowledging the expressed feelings. Active listening is now an accepted part of therapeutic counseling practices in many high schools, colleges, and clinics. The counselor listens attentively and interrupts only to restate and confirm feelings, to accept what is being expressed, or to seek clarification. The following brief excerpt between Rogers and a male client illustrates how he sought to provide a psychological mirror that would help clients see themselves more clearly.

Rogers: Feeling that now, hm? That you’re just no good to yourself, no good to anybody. Never will be any good to anybody. Just that you’re completely worthless, huh?—Those really are lousy feelings. Just feel that you’re no good at all, hm?

Client: Yeah. (*Muttering in low, discouraged voice*) That’s what this guy I went to town with just the other day told me.

Rogers: This guy that you went to town with really told you that you were no good? Is that what you’re saying? Did I get that right?

Client: M-hm.

Rogers: I guess the meaning of that if I get it right is that here’s somebody that—meant something to you and what does he think of you? Why, he’s told you that he thinks you’re no good at all. And that just really knocks the props out from under you. (*Client weeps quietly.*) It just brings the tears. (*Silence of 20 seconds*)

Client: (*Rather defiantly*) I don’t care though.

Rogers: You tell yourself you don’t care at all, but somehow I guess some part of you cares because some part of you weeps over it.

(Meador & Rogers, 1984, p. 167)

client-centered therapy

a humanistic therapy, developed by Carl Rogers, in which the therapist uses techniques such as active listening within a genuine, accepting, empathic environment to facilitate clients’ growth. (Also called *person-centered therapy*.)

active listening empathic listening in which the listener echoes, restates, and clarifies. A feature of Rogers’ client-centered therapy.

unconditional positive regard

a caring, accepting, nonjudgmental attitude, which Carl Rogers believed would help clients to develop self-awareness and self-acceptance.

Can a therapist be a perfect mirror, without selecting and interpreting what is reflected? Rogers conceded that one cannot be *totally* nondirective. Nevertheless, he believed that the therapist’s most important contribution is to accept and understand the client. Given a nonjudgmental, grace-filled environment that provides **unconditional positive regard**, people may accept even their worst traits and feel valued and whole.

Michael Rousier, Life Magazine. © Time Warner, Inc.

Active listening Carl Rogers (right) empathized with a client during this group therapy session.

If you want to listen more actively in your own relationships, three Rogerian hints may help:

1. **Paraphrase.** Rather than saying “I know how you feel,” check your understanding by summarizing the person’s words in your own words.
2. **Invite clarification.** “What might be an example of that?” may encourage the person to say more.
3. **Reflect feelings.** “It sounds frustrating” might mirror what you’re sensing from the person’s body language and intensity.

Before You Move On

▶ ASK YOURSELF

Think of your closest friends. Do they tend to express more empathy than those you don’t feel as close to? How have your own active listening skills changed as you’ve gotten older?

▶ TEST YOURSELF

In psychoanalysis, what does it mean when we refer to transference, resistance, and interpretation?

Answers to the Test Yourself questions can be found in Appendix E at the end of the book.

Module 70 Review

70-1 How do *psychotherapy*, *biomedical therapy*, and an *eclectic approach* to therapy differ?

- *Psychotherapy* is treatment involving psychological techniques; it consists of interactions between a trained therapist and someone seeking to overcome psychological difficulties or achieve personal growth.
- The major psychotherapies derive from psychology's psychodynamic, humanistic, behavioral, and cognitive perspectives.
- *Biomedical therapy* treats psychological disorders with medications or procedures that act directly on a patient's physiology.
- An *eclectic approach* combines techniques from various forms of psychotherapy.

70-2 What are the goals and techniques of psychoanalysis, and how have they been adapted in psychodynamic therapy?

- Through *psychoanalysis*, Sigmund Freud tried to give people self-insight and relief from their disorders by bringing anxiety-laden feelings and thoughts into conscious awareness.
 - Techniques included using free association and *interpretation* of instances of *resistance* and *transference*.
- Contemporary *psychodynamic therapy* has been influenced by traditional psychoanalysis but is briefer, less expensive, and more focused on helping the client find relief from current symptoms.
 - Therapists help clients understand themes that run through past and current relationships.
 - Interpersonal therapy is a brief 12- to 16-session form of psychodynamic therapy that has been effective in treating depression.

70-3 What are the basic themes of humanistic therapy, and what are the specific goals and techniques of Rogers' client-centered approach?

- Both psychoanalytic and humanistic therapies are *insight therapies*—they attempt to improve functioning by increasing clients' awareness of motives and defenses.
- Humanistic therapy's goals have included helping clients grow in self-awareness and self-acceptance; promoting personal growth rather than curing illness; helping clients take responsibility for their own growth; focusing on conscious thoughts rather than unconscious motivations; and seeing the present and future as more important than the past.
- Carl Rogers' *client-centered therapy* proposed that therapists' most important contributions are to function as a psychological mirror through *active listening* and to provide a growth-fostering environment of *unconditional positive regard*, characterized by genuineness, acceptance, and empathy.

Multiple-Choice Questions

1. Many clinical psychologists incorporate a variety of approaches into their therapy. They are said to take a(n) _____ approach.
 - a. transference
 - b. biomedical
 - c. psychoanalytic
 - d. eclectic
 - e. psychodynamic
2. What do psychodynamic therapists call the blocking of anxiety-laden material from the conscious?
 - a. Resistance
 - b. Interpretation
 - c. Transference
 - d. Face-to-face therapy
 - e. Interpersonal psychotherapy

- 3.** Which of the following is one of the ways humanistic therapies differ from psychoanalytic therapies?
- Humanist therapies believe the past is more important than the present and future.
 - Humanist therapies boost self-fulfillment by decreasing self-acceptance.
 - Humanist therapies believe the path to growth is found by uncovering hidden determinants.
 - Humanist therapies believe that unconscious thoughts are more important than conscious thoughts.
 - Humanist therapies focus on promoting growth, not curing illness.
- 4.** Which of the following is a feature of client-centered therapy?
- Free association
 - Active listening
 - Resistance
 - Freudian interpretation
 - Medical/biological treatment

Practice FRQs

1. Explain what psychoanalysis is, and then discuss the relationship of transference and resistance to the therapy.
2. Explain what client-centered therapy is, then describe the two major techniques of the therapy.

Answer

1 point: Psychoanalysis is a Freudian therapy that seeks to get patients to release repressed feelings to gain self-insight.

1 point: Transference is the patient's transfer of emotion to the analyst.

1 point: Resistance is the blocking of consciousness (by the patient) of anxiety-laden material.

(3 points)

Module 71

Behavior, Cognitive, and Group Therapies

Module Learning Objectives

- 71-1** Explain how the basic assumption of behavior therapy differs from those of psychodynamic and humanistic therapies, and describe the techniques used in exposure therapies and aversive conditioning.
- 71-2** State the main premise of therapy based on operant conditioning principles, and describe the views of its proponents and critics.
- 71-3** Discuss the goals and techniques of cognitive therapy and of cognitive-behavioral therapy.
- 71-4** Discuss the aims and benefits of group and family therapy.

Richard T. Nowitz/COORBIS

behavior therapy therapy that applies learning principles to the elimination of unwanted behaviors.

Behavior Therapies

- 71-1** How does the basic assumption of behavior therapy differ from those of psychodynamic and humanistic therapies? What techniques are used in exposure therapies and aversive conditioning?

The insight therapies assume that many psychological problems diminish as self-awareness grows. Psychodynamic therapies expect problems to subside as people gain insight into their unresolved and unconscious tensions. Humanistic therapies expect problems to diminish as people get in touch with their feelings. Proponents of **behavior therapy**, however, doubt the healing power of self-awareness. (You can become aware of why you are highly anxious during tests and still be anxious.) They assume that problem behaviors *are* the problems, and the application of learning principles can eliminate them. Rather than delving deeply below the surface looking for inner causes, therapies using behavioral techniques view maladaptive symptoms—such as phobias or sexual dysfunctions—as learned behaviors that can be replaced by constructive behaviors.

ScienceCartoonsPlus.com

AP® Exam Tip

Before you read the next several pages of this module, you may want to quickly review the material on classical and operant conditioning in Unit VI.

Classical Conditioning Techniques

One cluster of behavior therapies derives from principles developed in Ivan Pavlov's early twentieth-century conditioning experiments (Module 26). As Pavlov and others showed, we learn various behaviors and emotions through classical conditioning. Could maladaptive symptoms be examples of conditioned responses? If so, might reconditioning be a solution? Learning theorist O. H. Mowrer thought so and developed a successful conditioning therapy for chronic bed-wetters. The child sleeps on a liquid-sensitive pad connected to an alarm. Moisture on the pad triggers the alarm, waking the child. With sufficient repetition, this association of bladder relaxation with waking up stops the bed-wetting. In three out

of four cases the treatment is effective, and the success provides a boost to the child's self-image (Christophersen & Edwards, 1992; Houts et al., 1994).

Another example: If a claustrophobic fear of elevators is a learned aversion to the stimulus of being in a confined space, then might one unlearn that association by undergoing another round of conditioning to replace the fear response? **Counterconditioning** pairs the trigger stimulus (in this case, the enclosed space of the elevator) with a new response (relaxation) that is incompatible with fear. Indeed, behavior therapists have successfully counterconditioned people with such fears. Two specific counterconditioning techniques—*exposure therapy* and *aversive conditioning*—replace unwanted responses.

EXPOSURE THERAPIES

Picture this scene reported in 1924 by psychologist Mary Cover Jones: Three-year-old Peter is petrified of rabbits and other furry objects. Jones plans to replace Peter's fear of rabbits with a conditioned response incompatible with fear. Her strategy is to associate the fear-evoking rabbit with the pleasurable, relaxed response associated with eating.

As Peter begins his midafternoon snack, Jones introduces a caged rabbit on the other side of the huge room. Peter, eagerly munching away on his crackers and drinking his milk, hardly notices. On succeeding days, she gradually moves the rabbit closer and closer. Within two months, Peter is tolerating the rabbit in his lap, even stroking it while he eats. Moreover, his fear of other furry objects subsides as well, having been *countered*, or replaced, by a relaxed state that cannot coexist with fear (Fisher, 1984; Jones, 1924).

Unfortunately for those who might have been helped by her counterconditioning procedures, Jones' story of Peter and the rabbit did not immediately become part of psychology's lore. It was more than 30 years later that psychiatrist Joseph Wolpe (1958; Wolpe & Plaud, 1997) refined Jones' technique into what are now the most widely used types of behavior therapies: **exposure therapies**, which expose people to what they normally avoid or escape (behaviors that get reinforced by reduced anxiety). Exposure therapies have them face their fear, and thus overcome their fear of the fear response itself. As people can habituate to the sound of a train passing their new apartment, so, with repeated exposure, can they become less anxiously responsive to things that once petrified them (Rosa-Alcázar et al., 2008; Wolitzky-Taylor et al., 2008).

One widely used exposure therapy is **systematic desensitization**. Wolpe assumed, as did Jones, that you cannot be simultaneously anxious and relaxed. Therefore, if you can repeatedly relax when facing anxiety-provoking stimuli, you can gradually eliminate your anxiety. The trick is to proceed gradually. Let's see how this might work with social anxiety disorder. Imagine yourself afraid of public speaking. A therapist might first ask for your help in constructing a hierarchy of anxiety-triggering speaking situations. Yours might range from mildly anxiety-provoking situations, perhaps speaking up in a small group of friends, to panic-provoking situations, such as having to address a large audience.

Next, using *progressive relaxation*, the therapist would train you to relax one muscle group after another, until you achieve a blissful state of complete relaxation and comfort. Then the therapist would ask you to imagine, with your eyes closed, a mildly anxiety-arousing situation: You are having coffee with a group of friends and are trying to decide whether to speak up. If imagining the scene causes you to feel any anxiety, you would signal your tension by raising your finger, and the therapist would instruct you to switch off the mental image and go back to deep relaxation. This imagined scene is repeatedly paired with relaxation until you feel no trace of anxiety.

The therapist would progress up the constructed anxiety hierarchy, using the relaxed state to desensitize you to each imagined situation. After several sessions, you move to actual situations and practice what you had only imagined before, beginning with relatively easy tasks and gradually moving to more anxiety-filled ones. Conquering your anxiety in an actual situation, not just in your imagination, raises your self-confidence (Foa & Kozak, 1986; Williams, 1987). Eventually, you may even become a confident public speaker.

counterconditioning behavior therapy procedures that use classical conditioning to evoke new responses to stimuli that are triggering unwanted behaviors; include *exposure therapies* and *aversive conditioning*.

exposure therapies behavioral techniques, such as *systematic desensitization* and *virtual reality exposure therapy*, that treat anxieties by exposing people (in imagination or actual situations) to the things they fear and avoid.

systematic desensitization a type of exposure therapy that associates a pleasant, relaxed state with gradually increasing anxiety-triggering stimuli. Commonly used to treat phobias.

Bob Mahoney/The Image Works

Bob Mahoney/The Image Works

Virtual reality exposure therapy Virtual reality technology exposes people to vivid simulations of feared stimuli, such as a plane's takeoff.

virtual reality exposure therapy an anxiety treatment that progressively exposes people to electronic simulations of their greatest fears, such as airplane flying, spiders, or public speaking.

aversive conditioning a type of counterconditioning that associates an unpleasant state (such as nausea) with an unwanted behavior (such as drinking alcohol).

ing, heights, particular animals, and public speaking (Parsons & Rizzo, 2008). People who fear flying, for example, can peer out a virtual window of a simulated plane, feel vibrations, and hear the engine roar as the plane taxis down the runway and takes off. In studies comparing control groups with people experiencing virtual reality exposure therapy, the therapy has provided greater relief from real-life fear (Hoffman, 2004; Krijn et al., 2004).

Developments in virtual reality therapy suggest the likelihood of increasingly sophisticated simulated worlds in which people, using avatars (computer representations of themselves), try out new behaviors in virtual environments (Gorini, 2007). For example, someone with social anxiety disorder might visit virtual parties or group discussions, which others join over time.

AVERSIVE CONDITIONING

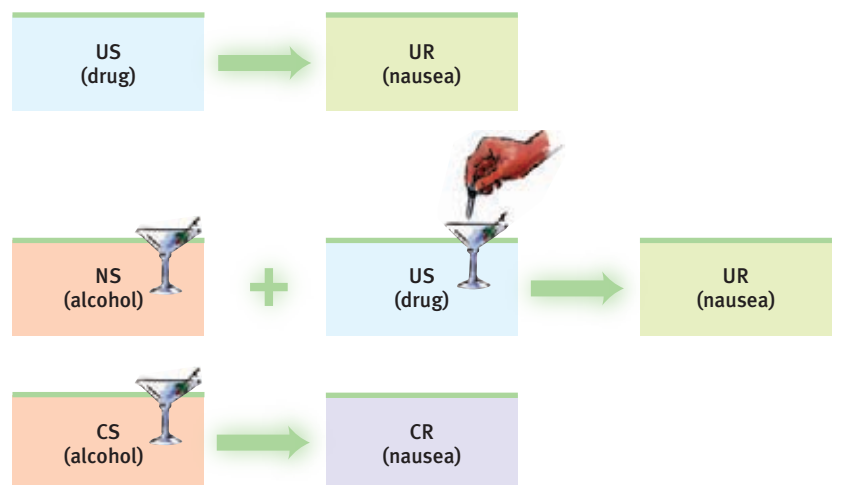

In systematic desensitization, the goal is substituting a positive (relaxed) response for a negative (fearful) response to a *harmless* stimulus. In **aversive conditioning**, the goal is substituting a negative (aversive) response for a positive response to a *harmful* stimulus (such as alcohol). Thus, aversive conditioning is the reverse of systematic desensitization—it seeks to condition an aversion to something the person *should* avoid.

The procedure is simple: It associates the unwanted behavior with unpleasant feelings. To treat nail biting, one can paint the fingernails with a nasty-tasting nail polish (Baskind, 1997). To treat alcohol use disorder, an aversion therapist offers the client appealing drinks laced with a drug that produces severe nausea. By linking alcohol with violent nausea (recall the taste-aversion experiments with rats and coyotes in Module 29), the therapist seeks to transform the person's reaction to alcohol from positive to negative (**FIGURE 71.1**).

Figure 71.1

Aversion therapy for alcohol use disorder

After repeatedly imbibing an alcoholic drink mixed with a drug that produces severe nausea, some people with a history of alcohol use disorder develop at least a temporary conditioned aversion to alcohol. (Remember: US is unconditioned stimulus, UR is unconditioned response, NS is neutral stimulus, CS is conditioned stimulus, and CR is conditioned response.)

Does aversive conditioning work? In the short run it may. Arthur Wiens and Carol Menustik (1983) studied 685 patients with alcohol use disorder who completed an aversion therapy program at a Portland, Oregon, hospital. One year later, after returning for several booster treatments of alcohol-sickness pairings, 63 percent were still successfully abstaining. But after three years, only 33 percent had remained abstinent.

The problem is that cognition influences conditioning. People know that outside the therapist's office they can drink without fear of nausea. Their ability to discriminate between the aversive conditioning situation and all other situations can limit the treatment's effectiveness. Thus, therapists often use aversive conditioning in combination with other treatments.

Operant Conditioning

71-2 What is the main premise of therapy based on operant conditioning principles, and what are the views of its proponents and critics?

Pioneering researcher B. F. Skinner helped us understand the basic concept in operant conditioning (Modules 27 and 28) that voluntary behaviors are strongly influenced by their consequences. Knowing this, today's therapists can practice *behavior modification*—reinforcing desired behaviors, and withholding reinforcement for undesired behaviors. Using operant conditioning to solve specific behavior problems has raised hopes for some otherwise hopeless cases. Children with intellectual disabilities have been taught to care for themselves. Socially withdrawn children with autism spectrum disorder (ASD) have learned to interact. People with schizophrenia have been helped to behave more rationally in their hospital ward. In such cases, therapists use positive reinforcers to shape behavior in a step-by-step manner, rewarding closer and closer approximations of the desired behavior.

In extreme cases, treatment must be intensive. One study worked with 19 withdrawn, uncommunicative 3-year-olds with ASD. Each participated in a 2-year program in which their parents spent 40 hours a week attempting to shape their behavior (Lovaas, 1987). The combination of positively reinforcing desired behaviors, and ignoring or punishing aggressive and self-abusive behaviors, worked wonders for some. By first grade, 9 of the 19 children were functioning successfully in school and exhibiting normal intelligence. In a group of 40 comparable children not undergoing this effortful treatment, only one showed similar improvement. (Ensuing studies suggested that positive reinforcement without punishment was most effective.)

Rewards used to modify behavior vary. For some people, the reinforcing power of attention or praise is sufficient. Others require concrete rewards, such as food. In institutional settings, therapists may create a **token economy**. When people display appropriate behavior, such as getting out of bed, washing, dressing, eating, talking coherently, cleaning up their rooms, or playing cooperatively, they receive a token or plastic coin as a positive reinforcer. Later, they can exchange their accumulated tokens for various rewards, such as candy, TV time, trips to town, or better living quarters. Token economies have been successfully applied in various settings (homes, classrooms, hospitals, institutions for juvenile offenders) and among members of various populations (including disturbed children and people with schizophrenia and other mental disabilities).

Critics of behavior modification express two concerns. The first is practical: *How durable are the behaviors?* Will people become so dependent on extrinsic rewards that the appropriate behaviors will stop when the reinforcers stop? Proponents of behavior modification believe the behaviors will endure if therapists wean patients from the tokens by shifting them toward other, real-life rewards, such as social approval. They also point out that the appropriate behaviors themselves can be intrinsically rewarding. For example, as a withdrawn person becomes more socially competent, the intrinsic satisfactions of social interaction may help the person maintain the behavior.

token economy an operant conditioning procedure in which people earn a token of some sort for exhibiting a desired behavior and can later exchange the tokens for various privileges or treats.

The second concern is ethical: *Is it right for one human to control another's behavior?* Those who set up token economies deprive people of something they desire and decide which behaviors to reinforce. To critics, this whole process has an authoritarian taint. Advocates reply that some patients request the therapy. Moreover, control already exists; rewards and punishers are already maintaining destructive behavior patterns. So why not reinforce adaptive behavior instead? Treatment with positive rewards is more humane than being institutionalized or punished, advocates argue, and the right to effective treatment and an improved life justifies temporary deprivation.

Cognitive Therapies

71-3 What are the goals and techniques of cognitive therapy and of cognitive-behavioral therapy?

AP® Exam Tip

Behavior therapies focus on what we do. Cognitive therapies focus on what we think. That's a very basic distinction, but it is critically important for your understanding.

We have seen how behavior therapies treat specific fears and problem behaviors. But how do they deal with major depression? Or with generalized anxiety disorder, in which anxiety has no focus and developing a hierarchy of anxiety-triggering situations is difficult? Therapists treating these less clearly defined psychological problems have had help from the same *cognitive revolution* that has profoundly changed other areas of psychology during the last half-century.

Lara Jo Regan

Cognitive therapy for eating disorders aided by journaling Cognitive therapists guide people toward new ways of explaining their good and bad experiences. By recording positive events and how she has enabled them, this woman may become more mindful of her self-control and more optimistic.

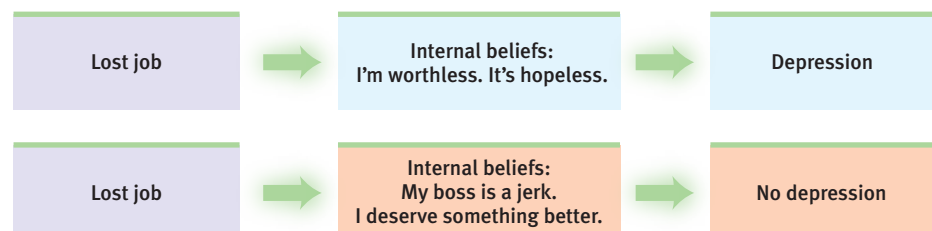

cognitive therapy therapy that teaches people new, more adaptive ways of thinking; based on the assumption that thoughts intervene between events and our emotional reactions.

"Life does not consist mainly, or even largely, of facts and happenings. It consists mainly of the storm of thoughts that are forever blowing through one's mind." -MARK TWAIN, 1835–1910

The **cognitive therapies** assume that our thinking colors our feelings (FIGURE 71.2). Between the event and our response lies the mind. Self-blaming and overgeneralized explanations of bad events are often an integral part of the vicious cycle of depression (see Module 67). The depressed person interprets a suggestion as criticism, disagreement as dislike, praise as flattery, friendliness as pity. Ruminating on such thoughts sustains the negative thinking. If such thinking patterns can be learned, then surely they can be replaced. Cognitive therapists therefore try in various ways to teach people new, more constructive ways of thinking. If people are miserable, they can be helped to change their minds.

Figure 71.2

A cognitive perspective on psychological disorders The person's emotional reactions are produced not directly by the event but by the person's thoughts in response to the event.

Rational-Emotive Behavior Therapy

According to Albert Ellis (1962, 1987, 1993), the creator of **rational-emotive behavior therapy (REBT)**, many problems arise from irrational thinking. For example, he described a disturbed woman and suggested how therapy might challenge her illogical, self-defeating assumptions (Ellis, 2011, pp. 198–199):

[She] does not merely believe it is undesirable if her lover rejects her. She tends to believe, also, that (a) it is awful; (b) she cannot stand it; (c) she should not, *must* not be rejected; (d) she will never be accepted by any desirable partner; (e) she is a worthless person because one lover has rejected her; and (f) she deserves to be rejected for being so worthless. Such common covert hypotheses are illogical, unrealistic, and destructive. . . . They can be easily elicited and demolished by any scientist worth his or her salt; and the rational-emotive therapist is exactly that: an exposing and nonsense-annihilating scientist.

Change people’s thinking by revealing the “absurdity” of their self-defeating ideas, the sharp-tongued Ellis believed, and you will change their self-defeating feelings and enable healthier behaviors.

Aaron Beck’s Therapy for Depression

Cognitive therapist Aaron Beck also believes that changing people’s thinking can change their functioning, though he has a gentler approach. Originally trained in Freudian techniques, Beck analyzed the dreams of depressed people. He found recurring negative themes of loss, rejection, and abandonment that extended into their waking thoughts. Such negativity even extends into therapy, as clients recall and rehearse their failings and worst impulses (Kelly, 2000). With cognitive therapy, Beck and his colleagues (1979) have sought to reverse clients’ *catastrophizing* beliefs about themselves, their situations, and their futures. Gentle questioning seeks to reveal irrational thinking, and then to persuade people to remove the dark glasses through which they view life (Beck et al., 1979, pp. 145–146):

Client: I agree with the descriptions of me but I guess I don’t agree that the way I think makes me depressed.

Beck: How do you understand it?

Client: I get depressed when things go wrong. Like when I fail a test.

Beck: How can failing a test make you depressed?

Client: Well, if I fail I’ll never get into law school.

Beck: So failing the test means a lot to you. But if failing a test could drive people into clinical depression, wouldn’t you expect everyone who failed the test to have a depression? . . . Did everyone who failed get depressed enough to require treatment?

Client: No, but it depends on how important the test was to the person.

Beck: Right, and who decides the importance?

Client: I do.

Beck: And so, what we have to examine is your way of viewing the test (or the way that you think about the test) and how it affects your chances of getting into law school. Do you agree?

Client: Right.

Beck: Do you agree that the way you interpret the results of the test will affect you? You might feel depressed, you might have trouble sleeping, not feel like eating, and you might even wonder if you should drop out of the course.

Client: I have been thinking that I wasn’t going to make it. Yes, I agree.

Beck: Now what did failing mean?

rational-emotive behavior therapy (REBT) a confrontational cognitive therapy, developed by Albert Ellis, that vigorously challenges people’s illogical, self-defeating attitudes and assumptions.

Client: (*tearful*) That I couldn't get into law school.

Beck: And what does that mean to you?

Client: That I'm just not smart enough.

Beck: Anything else?

Client: That I can never be happy.

Beck: And how do these thoughts make you feel?

Client: Very unhappy.

Beck: So it is the meaning of failing a test that makes you very unhappy. In fact, believing that you can never be happy is a powerful factor in producing unhappiness. So, you get yourself into a trap—by definition, failure to get into law school equals “I can never be happy.”

We often think in words. Therefore, getting people to change what they say to themselves is an effective way to change their thinking. Perhaps you can identify with the anxious students who, before a test, make matters worse with self-defeating thoughts: “This test’s probably going to be impossible. All these other students seem so relaxed and confident. wish I were better prepared. Anyhow, I’m so nervous I’ll forget everything.” To change such negative self-talk, Donald Meichenbaum (1977, 1985) offered *stress inoculation training*: teaching people to restructure their thinking in stressful situations. Sometimes it may be enough simply to say more positive things to oneself: “Relax. The test may be hard, but it will be hard for everyone else, too. I studied harder than most people. Besides, I don’t need a perfect score to get a good grade in this class.” After being trained to dispute their negative thoughts, depression-prone children, teens, and college students exhibit a greatly reduced rate of future depression (Seligman, 2002; Seligman et al., 2009). To a large extent, it is the thought that counts. **TABLE 71.1** provides a sampling of techniques commonly used in cognitive therapy.

Table 71.1 Selected Cognitive Therapy Techniques

Aim of Technique	Technique	Therapists' Directives
Reveal beliefs	Question your interpretations	Explore your beliefs, revealing faulty assumptions such as “I must be liked by everyone.”
	Rank thoughts and emotions	Gain perspective by ranking your thoughts and emotions from mildly to extremely upsetting.
Test beliefs	Examine consequences	Explore difficult situations, assessing possible consequences and challenging faulty reasoning.
	Decatastrophize thinking	Work through the actual worst-case consequences of the situation you face (it is often not as bad as imagined). Then determine how to cope with the real situation you face.
Change beliefs	Take appropriate responsibility	Challenge total self-blame and negative thinking, noting aspects for which you may be truly responsible, as well as aspects that aren't your responsibility.
	Resist extremes	Develop new ways of thinking and feeling to replace maladaptive habits. For example, change from thinking “I am a total failure” to “I got a failing grade on that paper, and I can make these changes to succeed next time.”

Cognitive-Behavioral Therapy

Cognitive-behavioral therapy (CBT), a widely practiced integrative therapy, aims not only to alter the way people think (cognitive therapy), but also to alter the way they act (behavior therapy). It seeks to make people aware of their irrational negative thinking, to replace it with new ways of thinking, *and to practice* the more positive approach in everyday settings. Behavioral change is typically addressed first, followed by sessions on cognitive change; the therapy concludes with a focus on maintaining both and preventing relapses.

Anxiety and mood disorders share a common problem: emotion regulation (Aldao & Nolen-Hoeksema, 2010). An effective CBT program for these emotional disorders trains people both to replace their catastrophizing thinking with more realistic appraisals, and, as homework, to practice behaviors that are incompatible with their problem (Kazantzis et al., 2010a,b; Moses & Barlow, 2006). A person might, for example, keep a log of daily situations associated with negative and positive emotions, and engage more in activities that lead them to feeling good. Or those who fear social situations might be assigned to practice approaching people.

CBT may also be useful with obsessive-compulsive disorder. In one study, people learned to prevent their compulsive behaviors by relabeling their obsessive thoughts (Schwartz et al., 1996). Feeling the urge to wash their hands again, they would tell themselves, “I’m having a compulsive urge,” and attribute it to their brain’s abnormal activity, as previously viewed in their PET scans. Instead of giving in to the urge, they would then spend 15 minutes in an enjoyable, alternative behavior, such as practicing an instrument, taking a walk, or gardening. This helped “unstick” the brain by shifting attention and engaging other brain areas. For two or three months, the weekly therapy sessions continued, with relabeling and refocusing practice at home. By the study’s end, most participants’ symptoms had diminished and their PET scans revealed normalized brain activity. Many other studies confirm CBT’s effectiveness for those with anxiety, depression, or anorexia nervosa (Covin et al., 2008; Mitte, 2005; Norton & Price, 2007). Studies have also found that cognitive-behavioral skills can be effectively taught and therapy conducted over the Internet (Barak et al., 2008; Kessler et al., 2009; Marks & Cavanaugh, 2009; Stross, 2011).

“The trouble with most therapy is that it helps you to feel better. But you don’t get better. You have to back it up with action, action, action.” -THERAPIST ALBERT ELLIS (1913–2007)

cognitive-behavioral therapy (CBT)

a popular integrative therapy that combines cognitive therapy (changing self-defeating thinking) with behavior therapy (changing behavior).

group therapy therapy conducted with groups rather than individuals, permitting therapeutic benefits from group interaction.

Group and Family Therapies

71-4 What are the aims and benefits of group and family therapy?

Group Therapy

Except for traditional psychoanalysis, most therapies may also occur in small groups. **Group therapy** does not provide the same degree of therapist involvement with each client. However, it offers benefits:

- *It saves therapists’ time and clients’ money*, often with no less effectiveness than individual therapy (Fuhrman & Burlingame, 1994).
- *It offers a social laboratory for exploring social behaviors and developing social skills.* Therapists frequently suggest group therapy for people experiencing frequent conflicts or whose behavior distresses others. For up to 90 minutes weekly, the therapist guides people’s interactions as they discuss issues and try out new behaviors.

Group Therapy ABC Family’s and *Seventeen Magazine*’s 2011 film *Cyberbully* realistically portrayed main characters attending group therapy, where they found they were not alone in their troublesome feelings.

Photograph Courtesy of Muse Entertainment Enterprises Inc.

- *It enables people to see that others share their problems.* It can be a relief to discover that you are not alone—to learn that others, despite their composure, experience some of the same troublesome feelings and behaviors.
- *It provides feedback as clients try out new ways of behaving.* Hearing that you look poised, even though you feel anxious and self-conscious, can be very reassuring.

Family Therapy

One special type of group interaction, **family therapy**, assumes that no person is an island: We live and grow in relation to others, especially our families. We struggle to differentiate ourselves from our families, but we also need to connect with them emotionally. Some of our problem behaviors arise from the tension between these two tendencies, which can create family stress.

Unlike most psychotherapy, which focuses on what happens inside the person's own skin, family therapists work with multiple family members to heal relationships and to mobilize family resources. They tend to view the family as a system in which each person's actions trigger reactions from others, and they help family members discover their role within their family's social system. A child's rebellion, for example, affects and is affected by other family tensions. Therapists also attempt—usually with some success, research suggests—to open up communication within the family or to help family members discover new ways of preventing or resolving conflicts (Hazelrigg et al., 1987; Shadish et al., 1993).

Self-Help Groups

Many people also participate in self-help and support groups (Yalom, 1985). One analysis of online support groups and more than 14,000 self-help groups reported that most support groups focus on stigmatized or hard-to-discuss illnesses (Davison et al., 2000). AIDS patients, for example, are 250 times more likely than hypertension patients to be in support groups. Those struggling with anorexia and alcohol use disorder often join groups; those with migraines and ulcers usually do not. People with hearing loss have national organizations with local chapters; people with vision loss more often cope on their own.

The grandparent of support groups, Alcoholics Anonymous (AA), reports having more than 2 million members in 114,000 groups worldwide. Its famous 12-step program, emulated by many other self-help groups, asks members to admit their powerlessness, to seek help from a higher power and from one another, and (the twelfth step) to take the message to others in need of it. In one eight-year, \$27 million investigation, AA participants reduced their drinking sharply, although so did those assigned to cognitive-behavioral therapy or to “motivational therapy” (Project Match, 1997). Other studies have similarly found that 12-step programs such as AA have helped reduce alcohol use disorder comparably with other treatment interventions (Ferri et al., 2006; Moos & Moos, 2005). The more meetings members attend, the greater their alcohol abstinence (Moos & Moos, 2006). In one study of 2300 veterans who sought treatment for alcohol use disorder, a high level of AA involvement was followed by diminished alcohol problems (McKellar et al., 2003).

In an individualistic age, with more and more people living alone or feeling isolated, the popularity of support groups—for the addicted, the bereaved, the divorced, or simply those seeking fellowship and growth—seems to reflect a longing for community and connectedness. More than 100 million Americans belong to small religious, interest, or self-help groups that meet regularly—and 9 in 10 report that group members “support each other emotionally” (Gallup, 1994).

* * *

For a synopsis of the modern forms of psychotherapy we've been discussing, see **TABLE 71.2**.

FYI

With more than 2 million members worldwide, AA is said to be “the largest organization on Earth that nobody wanted to join” (Finlay, 2000).

family therapy therapy that treats the family as a system. Views an individual's unwanted behaviors as influenced by, or directed at, other family members.

Table 71.2 Comparing Modern Psychotherapies

Therapy	Presumed Problem	Therapy Aim	Therapy Technique
<i>Psychodynamic</i>	Unconscious conflicts from childhood experiences	Reduce anxiety through self-insight.	Interpret patients' memories and feelings.
<i>Client-centered</i>	Barriers to self-understanding and self-acceptance	Enable growth via unconditional positive regard, genuineness, and empathy.	Listen actively and reflect clients' feelings.
<i>Behavior</i>	Dysfunctional behaviors	Relearn adaptive behaviors; extinguish problem ones.	Use classical conditioning (via exposure or aversion therapy) or operant conditioning (as in token economies).
<i>Cognitive</i>	Negative, self-defeating thinking	Promote healthier thinking and self-talk.	Train people to dispute negative thoughts and attributions.
<i>Cognitive-behavioral</i>	Self-harmful thoughts and behaviors	Promote healthier thinking and adaptive behaviors.	Train people to counter self-harmful thoughts and to act out their new ways of thinking.
<i>Group and family</i>	Stressful relationships	Heal relationships.	Develop an understanding of family and other social systems, explore roles, and improve communication.

Before You Move On

▶ ASK YOURSELF

Critics say that behavior modification techniques, such as those used in token economies, are inhumane. Do you agree or disagree? Why?

▶ TEST YOURSELF

What is the major distinction between the underlying assumptions in insight therapies and in behavior therapies?

Answers to the Test Yourself questions can be found in Appendix E at the end of the book.

Module 71 Review

71-1 How does the basic assumption of behavior therapy differ from those of psychodynamic and humanistic therapies? What techniques are used in exposure therapies and aversive conditioning?

- *Behavior therapies* are not insight therapies. Their goal is to apply learning principles to modify problem behaviors.
- Classical conditioning techniques, including *exposure therapies* (such as *systematic desensitization* or *virtual reality exposure therapy*) and *aversive conditioning*, attempt to change behaviors through *counterconditioning*—evoking new responses to old stimuli that trigger unwanted behaviors.

71-2 What is the main premise of therapy based on operant conditioning principles, and what are the views of its proponents and critics?

- Therapy based on operant conditioning principles uses behavior modification techniques to change unwanted behaviors through positively reinforcing desired behaviors and ignoring or punishing undesirable behaviors.
- Critics maintain that (1) techniques such as those used in *token economies* may produce behavior changes that disappear when rewards end, and (2) deciding which behaviors should change is authoritarian and unethical.
- Proponents argue that treatment with positive rewards is more humane than punishing people or institutionalizing them for undesired behaviors.

71-3 What are the goals and techniques of cognitive therapy and of cognitive-behavioral therapy?

- The *cognitive therapies*, such as Aaron Beck's cognitive therapy for depression, assume that our thinking influences our feelings, and that the therapist's role is to change clients' self-defeating thinking by training them to view themselves in more positive ways.
- *Rational-emotive behavior therapy (REBT)* is a confrontational cognitive therapy that actively challenges irrational beliefs.
- The widely researched and practiced *cognitive-behavioral therapy (CBT)* combines cognitive therapy and behavior therapy by helping clients regularly act out their new ways of thinking and talking in their everyday life.

71-4 What are the aims and benefits of group and family therapy?

- *Group therapy* sessions can help more people and costs less per person than individual therapy would. Clients may benefit from exploring feelings and developing social skills in a group situation, from learning that others have similar problems, and from getting feedback on new ways of behaving.
- *Family therapy* views a family as an interactive system and attempts to help members discover the roles they play and to learn to communicate more openly and directly.

Multiple-Choice Questions

1. Dr. Welle tries to help her clients by teaching them to modify the things they do when under stress or experiencing symptoms. This means that Dr. Welle engages in _____ therapy.
 - a. behavior
 - b. cognitive
 - c. group
 - d. rational-emotive behavior
 - e. client-centered
2. Mary Cover Jones helped a little boy named Peter overcome his fear of rabbits by gradually moving a rabbit closer to him each day while he was eating his snack. This was one of the first applications of
 - a. group therapy.
 - b. virtual reality exposure therapy.
 - c. aversive therapy.
 - d. exposure therapy.
 - e. cognitive therapy.

- 3.** On which of the following are token economies based?
- Classical conditioning
 - Operant conditioning
 - Group therapy
 - Cognitive therapy
 - Cognitive-behavioral therapy
- 4.** Which of the following is considered a benefit of group therapy?
- It is the most effective therapy for children.
 - It is particularly effective in the treatment of antisocial personality disorder.
 - It is particularly effective in the treatment of schizophrenia.
 - It is the only setting proven effective for virtual reality exposure therapy.
 - It saves time and money when compared with other forms of therapy.

Practice FRQs

- 1.** Name and describe two specific types of group therapy.

Answer

1 point: Family therapy is a means of treating an entire family as an interdependent system.

1 point: Self-help groups, such as Alcoholics Anonymous (AA), are groups of individuals who share a similar problem working together to overcome that problem.

- 2.** Explain what systematic desensitization is, then describe the two major components of the therapy.

(3 points)

Module 72

Evaluating Psychotherapies and Prevention Strategies

Module Learning Objectives

- 72-1** Discuss whether psychotherapy works as interpreted by clients, clinicians, and outcome research.
- 72-2** Describe which psychotherapies are most effective for specific disorders.
- 72-3** Discuss how alternative therapies fare under scientific scrutiny.
- 72-4** Describe the three elements shared by all forms of psychotherapy.
- 72-5** Discuss how culture, gender, and values influence the therapist-client relationship.
- 72-6** Identify some guidelines for selecting a therapist.
- 72-7** Explain the rationale of preventive mental health programs.

Evaluating Psychotherapies

Advice columnists frequently urge their troubled letter writers to get professional help: “Don’t give up. Find a therapist who can help you. Make an appointment.”

Many Americans share this confidence in psychotherapy’s effectiveness. Before 1950, psychiatrists were the primary providers of mental health care. Today’s providers include clinical and counseling psychologists; clinical social workers; clergy; marital and school counselors; and psychiatric nurses. With such an enormous outlay of time as well as money, effort, and hope, it is important to ask: Are the millions of people worldwide justified in placing their hopes in psychotherapy?

Is Psychotherapy Effective?

- 72-1** Does psychotherapy work? Who decides?

The question, though simply put, is not simple to answer. Measuring therapy’s effectiveness is not like taking your body’s temperature to see if your fever has gone away. If you and I were to undergo psychotherapy, how would we assess its effectiveness? By how we feel about our progress? By how our therapist feels about it? By how our friends and family feel about it? By how our behavior has changed?

CLIENTS' PERCEPTIONS

If clients' testimonials were the only measuring stick, we could strongly affirm the effectiveness of psychotherapy. When 2900 *Consumer Reports* readers (1995; Kotkin et al., 1996; Seligman, 1995) related their experiences with mental health professionals, 89 percent said they were at least "fairly well satisfied." Among those who recalled feeling *fair* or *very poor* when beginning therapy, 9 in 10 now were feeling *very good*, *good*, or at least *so-so*. We have their word for it—and who should know better?

We should not dismiss these testimonials lightly. But for several reasons, client testimonials do not persuade psychotherapy's skeptics:

- **People often enter therapy in crisis.** When, with the normal ebb and flow of events, the crisis passes, people may attribute their improvement to the therapy.
- **Clients may need to believe the therapy was worth the effort.** To admit investing time and money in something ineffective is like admitting to having one's car serviced repeatedly by a mechanic who never fixes it. Self-justification is a powerful human motive.
- **Clients generally speak kindly of their therapists.** Even if the problems remain, say the critics, clients "work hard to find something positive to say. The therapist had been very understanding, the client had gained a new perspective, he learned to communicate better, his mind was eased, anything at all so as not to have to say treatment was a failure" (Zilbergeld, 1983, p. 117).

As earlier units document, we are prone to selective and biased recall and to making judgments that confirm our beliefs. Consider the testimonials gathered in a massive experiment with over 500 Massachusetts boys, aged 5 to 13 years, many of whom seemed bound for delinquency. By the toss of a coin, half the boys were assigned to a 5-year treatment program. The treated boys were visited by counselors twice a month. They participated in community programs, and they received academic tutoring, medical attention, and family assistance as needed. Some 30 years later, Joan McCord (1978, 1979) located 485 participants, sent them questionnaires, and checked public records from courts, mental hospitals, and other sources. Was the treatment successful?

Client testimonials yielded encouraging results, even glowing reports. Some men noted that, had it not been for their counselors, "I would probably be in jail," "My life would have gone the other way," or "I think I would have ended up in a life of crime." Court records offered apparent support: Even among the "difficult" boys in the treatment group, 66 percent had no official juvenile crime record.

But recall psychology's most powerful tool for sorting reality from wishful thinking: the *control group*. For every boy in the treatment group, there was a similar boy in a control group, receiving no counseling. Of these untreated men, 70 percent had no juvenile record. On several other measures, such as a record of having committed a second crime, alcohol use disorder, death rate, and job satisfaction, the untreated men exhibited slightly *fewer* problems. The glowing testimonials of those treated had been unintentionally deceiving.

CLINICIANS' PERCEPTIONS

Do clinicians' perceptions give us any more reason to celebrate? Case studies of successful treatment abound. The problem is that clients justify entering psychotherapy by emphasizing their unhappiness and justify leaving by emphasizing their well-being. Therapists treasure compliments from clients as they say good-bye or later express their gratitude, but they hear little from clients who experience only temporary relief and seek out new therapists for their recurring problems. Thus, the same person—with the same recurring anxieties, depression, or marital difficulty—may be a "success" story in several therapists' files.

Because people enter therapy when they are extremely unhappy, and usually leave when they are less extremely unhappy, most therapists, like most clients, testify to therapy's success—regardless of the treatment (see Thinking Critically About: "Regressing" From Unusual to Usual on the next page).

Feng Li/Getty Images

Trauma These women were mourning the tragic loss of lives and homes in the 2010 earthquake in China. Those who suffer through such trauma may benefit from counseling, though many people recover on their own, or with the help of supportive relationships with family and friends. "Life itself still remains a very effective therapist," noted psychodynamic therapist Karen Horney (*Our Inner Conflicts*, 1945).

Thinking Critically About

“Regressing” From Unusual to Usual

Clients' and therapists' perceptions of therapy's effectiveness are vulnerable to inflation from two phenomena. One is the *placebo effect*—the power of belief in a treatment. If you think a treatment is going to be effective, it just may be (thanks to the healing power of your positive expectations).

The second phenomenon is **regression toward the mean**—the tendency for unusual events (or emotions) to “regress” (return) to their average state. Thus, extraordinary happenings (feeling low) tend to be followed by more ordinary ones (a return to our more usual state). Indeed, when things hit bottom, whatever we try—going to a psychotherapist, starting yoga, doing aerobic exercise—is more likely to be followed by improvement than by further descent.

“Once you become sensitized to it, you see regression everywhere.”

Psychologist Daniel Kahneman (1985)

The point may seem obvious, yet we regularly miss it: We sometimes attribute what may be a normal regression (the expected return to normal) to something we have done. Consider:

- Students who score much lower or higher on a test than they usually do are likely, when retested, to return toward their average.
- Unusual ESP subjects who defy chance when first tested nearly always lose their “psychic powers” when retested (a phenomenon parapsychologists have called the decline effect).
- Coaches often yell at their players after an unusually bad first half. They may then feel rewarded for having done so when the team's performance improves (returns to normal) during the second half.

In each case, the cause-effect link may be genuine. Each may, however, be an instance of the natural tendency for behavior to regress from the unusual to the more usual. And this defines the task for therapy-efficacy research: Does the client's improvement following a particular therapy exceed what could be expected from the placebo and regression effects alone, shown by comparison with control groups?

regression toward the mean the tendency for extreme or unusual scores to fall back (regress) toward their average.

OUTCOME RESEARCH

How, then, can we objectively measure the effectiveness of psychotherapy if neither clients nor clinicians can tell us? How can we determine which people and problems are best helped, and by what type of psychotherapy?

In search of answers, psychologists have turned to controlled research studies. Similar research in the 1800s transformed the field of medicine. Physicians, skeptical of many of the fashionable treatments (bleeding, purging, infusions of plant and metal substances), began to realize that many patients got better on their own, without these treatments, and that others died despite them. Sorting fact from superstition required observing patients with and without a particular treatment. Typhoid fever patients, for example, often improved after being bled, convincing most physicians that the treatment worked. Not until a control group was given mere bed rest—and 70 percent were observed to improve after five weeks of fever—did physicians learn, to their shock, that the bleeding was worthless (Thomas, 1992).

In psychology, the opening challenge to the effectiveness of psychotherapy was issued by British psychologist Hans Eysenck (1952). Launching a spirited debate, he summarized studies showing that two-thirds of those receiving psychotherapy for nonpsychotic disorders improved markedly. To this day, no one disputes that optimistic estimate.

Why, then, are we still debating psychotherapy's effectiveness? Because Eysenck also reported similar improvement among *untreated* persons, such as those who were on waiting lists. With or without psychotherapy, he said, roughly two-thirds improved noticeably. Time was a great healer.

Later research revealed shortcomings in Eysenck's analyses; his sample was small (only 24 studies of psychotherapy outcomes in 1952). Today, hundreds of studies are available. The best are *randomized clinical trials*, in which researchers randomly assign people on a waiting list to therapy or to no therapy, and later evaluate everyone, using tests and assessments

by others who don't know whether therapy was given. The results of many such studies are then digested by means of **meta-analysis**, a statistical procedure that combines the conclusions of a large number of different studies. Simply said, meta-analyses give us the bottom-line results of lots of studies.

Psychotherapists welcomed the first meta-analysis of some 475 psychotherapy outcome studies (Smith et al., 1980). It showed that the average therapy client ends up better off than 80 percent of the untreated individuals on waiting lists (**FIGURE 72.1**). The claim is modest—by definition, about 50 percent of untreated people also are better off than the average untreated person. Nevertheless, Mary Lee Smith and her colleagues exulted that “psychotherapy benefits people of all ages as reliably as schooling educates them, medicine cures them, or business turns a profit” (p. 183).

AP® Exam Tip

You will need to understand what basic statistical concepts are, but you will not need to do any actual calculations on the AP® exam.

Figure 72.1

Treatment versus no treatment

These two normal distribution curves based on a meta-analysis (combining data from 475 studies) show the improvement of untreated people and psychotherapy clients. The outcome for the average therapy client surpassed that for 80 percent of the untreated people. (Adapted from Smith et al., 1980.)

Dozens of subsequent summaries have now examined this question. Their verdict echoes the results of the earlier outcome studies: *Those not undergoing therapy often improve, but those undergoing therapy are more likely to improve more quickly, and with less risk of relapse.*

Is psychotherapy also cost-effective? Again, the answer is *Yes*. Studies show that when people seek psychological treatment, their search for other medical treatment drops—by 16 percent in one digest of 91 studies (Chiles et al., 1999). Given the staggering annual cost of psychological disorders and substance abuse—including crime, accidents, lost work, and treatment—psychotherapy is a good investment, much like money spent on prenatal and well-baby care. Both *reduce* long-term costs. Boosting employees' psychological well-being, for example, can lower medical costs, improve work efficiency, and diminish absenteeism.

But note that the claim—that psychotherapy, *on average*, is somewhat effective—refers to no one therapy in particular. It is like reassuring lung-cancer patients that “on average,” medical treatment of health problems is effective. What people want to know is the effectiveness of a *particular* treatment for their specific problems.

meta-analysis a procedure for statistically combining the results of many different research studies.

The Relative Effectiveness of Different Psychotherapies

72-2

Are some psychotherapies more effective than others for specific disorders?

So what can we tell people considering psychotherapy, and those paying for it, about *which* psychotherapy will be most effective for their problem? The statistical summaries and surveys fail to pinpoint any one type of therapy as generally superior (Smith et al., 1977, 1980). Clients seemed equally satisfied, *Consumer Reports* concluded, whether treated by a psychiatrist,

“Whatever differences in treatment efficacy exist, they appear to be extremely small, at best.” -BRUCE WAMPOLD ET AL., 1997

“Different sores have different salves.” -ENGLISH PROVERB

evidence-based practice

clinical decision making that integrates the best available research with clinical expertise and patient characteristics and preferences.

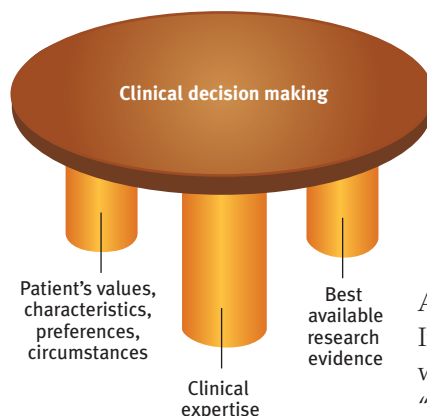

Figure 72.2

Evidence-based clinical decision making The ideal clinical decision making is a three-legged stool, upheld by research evidence, clinical expertise, and knowledge of the patient.

psychologist, or social worker; whether seen in a group or individual context; whether the therapist had extensive or relatively limited training and experience (Seligman, 1995). Other studies concur. There is little if any connection between clinicians' experience, training, supervision, and licensing and their clients' outcomes (Luborsky et al., 2002; Wampold, 2007).

So, was the dodo bird in Alice in Wonderland right: “Everyone has won and all must have prizes”? Not quite. Some forms of therapy get prizes for particular problems, though there is often an overlapping—or comorbidity—of disorders. Behavioral conditioning therapies, for example, have achieved especially favorable results with specific behavior problems, such as bed-wetting, phobias, compulsions, marital problems, and sexual dysfunctions (Baker et al., 2008; Hunsley & DiGiulio, 2002; Shadish & Baldwin, 2005). Psychodynamic therapy has helped treat depression and anxiety (Driessen et al., 2010; Leichsenring & Rabung, 2008; Shedler, 2010b). And new studies confirm cognitive and cognitive-behavioral therapy's effectiveness in coping with anxiety, posttraumatic stress disorder, and depression (Baker et al., 2008; De Los Reyes & Kazdin, 2009; Stewart & Chambless, 2009; Tolin, 2010).

Moreover, we can say that therapy is most effective when the problem is clear-cut (Singer, 1981; Westen & Morrison, 2001). Those who experience phobias or panic and those who are unassertive can hope for improvement. Those with less-focused problems, such as depression and anxiety, usually benefit in the short term but often relapse later. And those with the negative symptoms of chronic schizophrenia or a desire to change their entire personality are unlikely to benefit from therapy alone (Pfammatter et al., 2006; Zilbergeld, 1983). The more specific the problem, the greater the hope.

But no prizes—and little or no scientific support—go to certain other therapies (Arkowitz & Lilienfeld, 2006). We would all therefore be wise to avoid energy therapies that propose to manipulate people's invisible energy fields, recovered-memory therapies that aim to unearth “repressed memories” of early child abuse (Module 33), and rebirthing therapies that engage people in reenacting the supposed trauma of their birth.

As with some medical treatments, it's possible for psychological treatments not only to be ineffective but harmful—by making people worse or preventing their getting better (Barlow, 2010; Castonguay et al., 2010; Dimidjian & Hollon, 2010). The National Science and Technology Council cites the Scared Straight program (seeking to deter children and youth from crime) as an example of well-intentioned programs that have proved ineffective or even harmful. The evaluation question—which therapies get prizes and which do not?—lies at the heart of what some call psychology's civil war. To what extent should science guide both clinical practice and the willingness of health care providers and insurers to pay for therapy?

On the one side are research psychologists using scientific methods to extend the list of well-defined and validated therapies for various disorders. They decry clinicians who “give more weight to their personal experiences” (Baker et al., 2008). On the other side are nonscientist therapists who view their practice as more art than science, saying that people are too complex and therapy too intuitive to describe in a manual or test in an experiment. Between these two factions stand the science-oriented clinicians, who aim to base practice on evidence and make mental health professionals accountable for effectiveness.

To encourage **evidence-based practice** in psychology, the American Psychological Association and others (2006; Baker et al., 2008; Levant & Hasan, 2008) have followed the Institute of Medicine's lead, advocating that clinicians integrate the best available research with clinical expertise and with patient preferences and characteristics. Available therapies “should be rigorously evaluated” and then applied by clinicians who are mindful of their skills and of each patient's unique situation (**FIGURE 72.2**). Increasingly, insurer and government support for mental health services requires evidence-based practice. In 2007, for example, Britain's National Health Service announced that it would pour the equivalent of \$600 million into training new mental health workers in evidence-based practices (such as cognitive-behavioral therapy) and to disseminating information about such treatments (DeAngelis, 2008).

Evaluating Alternative Therapies

72-3 How do alternative therapies fare under scientific scrutiny?

The tendency of many abnormal states of mind to regress to normal, combined with the placebo effect, creates fertile soil for pseudotherapies. Bolstered by anecdotes, heralded by the media, and broadcast on the Internet, alternative therapies can spread like wildfire. In one national survey, 57 percent of those with a history of anxiety attacks and 54 percent of those with a history of depression had used alternative treatments, such as herbal medicine, massage, and spiritual healing (Kessler et al., 2001).

Testimonials aside, what does the evidence say? This is a tough question, because there is no evidence for or against most of them, though their proponents often feel personal experience is evidence enough. Some, however, have been the subject of controlled research. Let's consider two of them. As we do, remember that sifting sense from nonsense requires the scientific attitude: being skeptical but not cynical, open to surprises but not gullible.

EYE MOVEMENT DESENSITIZATION AND REPROCESSING (EMDR)

EMDR (eye movement desensitization and reprocessing) is a therapy adored by thousands and dismissed by thousands more as a sham—"an excellent vehicle for illustrating the differences between scientific and pseudoscientific therapy techniques," suggested James Herbert and seven others (2000). Francine Shapiro (1989, 2007) developed EMDR while walking in a park and observing that anxious thoughts vanished as her eyes spontaneously darted about. Offering her novel anxiety treatment to others, she had people imagine traumatic scenes while she triggered eye movements by waving her finger in front of their eyes, supposedly enabling them to unlock and reprocess previously frozen memories. Tens of thousands of mental health professionals from more than 75 countries have since undergone training (EMDR, 2011). Not since the similarly charismatic Franz Anton Mesmer introduced *animal magnetism* (hypnosis) more than two centuries ago (also after feeling inspired by an outdoor experience) has a new therapy attracted so many devotees so quickly.

Does it work? For 84 to 100 percent of single-trauma victims participating in four studies, the answer is *Yes*, reports Shapiro (1999, 2002). Moreover, the treatment need take no more than three 90-minute sessions. The Society of Clinical Psychology task force on empirically validated treatments acknowledges that EMDR is "probably efficacious" for the treatment of nonmilitary posttraumatic stress disorder (Chambless et al., 1997; see also Bisson & Andrew, 2007; Rodenburg et al., 2009; Seidler & Wagner, 2006).

Why, wonder the skeptics, would rapidly moving one's eyes while recalling traumas be therapeutic? Some argue that eye movements serve to relax or distract patients, thus allowing the memory-associated emotions to extinguish (Gunter & Bodner, 2008). Others believe that eye movements in themselves are *not* the therapeutic ingredient. Trials in which people imagined traumatic scenes and tapped a finger, or just stared straight ahead while the therapist's finger wagged, have produced therapeutic results (Deville, 2003). EMDR does work better than doing nothing, acknowledge the skeptics (Lilienfeld & Arkowitz, 2007b), but many suspect that what is therapeutic is the combination of exposure therapy—repeatedly associating with traumatic memories a safe and reassuring context that provides some emotional distance from the experience—and a robust placebo effect. Had Mesmer's pseudotherapy been compared with no treatment at all, it, too (thanks to the healing power of positive belief), might have been found "probably efficacious," observed Richard McNally (1999).

LIGHT EXPOSURE THERAPY

Have you ever found yourself oversleeping, gaining weight, and feeling lethargic during the dark mornings and overcast days of winter? There likely was a survival advantage to your distant ancestors' slowing down and conserving energy during the dark days of winter. For some people, however, especially women and those living far from the equator, the wintertime

"Studies indicate that EMDR is just as effective with fixed eyes. If that conclusion is right, what's useful in the therapy (chiefly behavioral desensitization) is not new, and what's new is superfluous." -HARVARD MENTAL HEALTH LETTER, 2002

© Kathryn LeMieux, distributed by King Features Syndicate

blahs constitute a seasonal pattern for major depressive disorder. To counteract these dark spirits, National Institute of Mental Health researchers the early 1980s had an idea: Give people a timed daily dose of intense light. Sure enough, people reported they felt better.

Was this a bright idea, or another dim-witted example of the placebo effect? Research sheds some light. One study exposed some people with a seasonal pattern in their depression symptoms to 90 minutes of bright light and others to a sham placebo treatment—a hissing “negative ion generator” about which the staff expressed similar enthusiasm (but which was

not even turned on). After four weeks, 61 percent of those exposed to morning light had greatly improved, as had 50 percent of those exposed to evening light and 32 percent of those exposed to the placebo (Eastman et al., 1998). Other studies have found that 30 minutes of exposure to 10,000-lux white fluorescent light produced relief for more than half the people receiving morning light therapy (Flory et al., 2010; Terman et al., 1998, 2001). From 20 carefully controlled trials we have a verdict (Golden et al., 2005; Wirz-Justice, 2009): Morning bright light does indeed dim depression symptoms for many of those suffering in a seasonal pattern. Moreover, it does so as effectively as taking antidepressant drugs or undergoing cognitive-behavioral therapy (Lam et al., 2006; Rohan et al., 2007). The effects are clear in brain scans; light therapy sparks activity in a brain region that influences the body’s arousal and hormones (Ishida et al., 2005).

BSIP SA/Alamy

Light therapy To counteract winter depression, some people spend time each morning exposed to intense light that mimics natural outdoor light. Light boxes with the appropriate intensity are available from health supply and lighting stores.

Commonalities Among Psychotherapies

72-4 What three elements are shared by all forms of psychotherapy?

Why have studies found little correlation between therapists’ training and experience and clients’ outcomes? In search of some answers, Jerome Frank (1982), Marvin Goldfried (Goldfried & Padawer, 1982), Hans Strupp (1986), and Bruce Wampold (2001, 2007) have studied the common ingredients of various therapies. They suggest that all therapies offer at least three benefits:

- **Hope for demoralized people** People seeking therapy typically feel anxious, depressed, devoid of self-esteem, and incapable of turning things around. What any therapy offers is the expectation that, with commitment from the therapy seeker, things can and will get better. This belief, apart from any therapeutic technique, may function as a placebo, improving morale, creating feelings of self-efficacy, and diminishing symptoms (Prioleau et al., 1983).
- **A new perspective** Every therapy also offers people a plausible explanation of their symptoms and an alternative way of looking at themselves or responding to their world. Armed with a believable fresh perspective, they may approach life with a new attitude, open to making changes in their behaviors and their views of themselves.
- **An empathic, trusting, caring relationship** To say that therapy outcome is unrelated to training and experience is not to say all *therapists* are equally effective. No matter what therapeutic technique they use, effective therapists are empathic people who seek to understand another’s experience; who communicate their care and concern to the client; and who earn the client’s trust through respectful listening, reassurance, and advice. Marvin Goldfried and his associates (1998) found these qualities in recorded therapy sessions from 36 recognized master therapists. Some took a

cognitive-behavioral approach, others emphasized psychodynamic teachings. Regardless, the striking finding was how *similar* they were. At key moments, the empathic therapists of both persuasions would help clients evaluate themselves, link one aspect of their life with another, and gain insight into their interactions with others.

The emotional bond between therapist and client—the **therapeutic alliance**—is a key aspect of effective therapy (Klein et al., 2003; Wampold, 2001). One U.S. National Institute of Mental Health depression-treatment study confirmed that the most effective therapists were those who were perceived as most empathic and caring and who established the closest therapeutic bonds with their clients (Blatt et al., 1996). That all therapies offer hope through a fresh perspective offered by a caring person is what also enables paraprofessionals (briefly trained caregivers) to assist so many troubled people so effectively (Christensen & Jacobson, 1994).

These three common elements are also part of what the growing numbers of self-help and support groups offer their members. And they are part of what traditional healers have offered (Jackson, 1992). Healers everywhere—special people to whom others disclose their suffering, whether psychiatrists, witch doctors, or shamans—have listened in order to understand and to empathize, reassure, advise, console, interpret, or explain (Torrey, 1986). Such qualities may explain why people who feel supported by close relationships—who enjoy the fellowship and friendship of caring people—are less likely to need or seek therapy (Frank, 1982; O'Connor & Brown, 1984).

* * *

To recap, people who seek help usually improve. So do many of those who do not undergo psychotherapy, and that is a tribute to our human resourcefulness and our capacity to care for one another. Nevertheless, though the therapist's orientation and experience appear not to matter much, people who receive some psychotherapy usually improve more than those who do not. People with clear-cut, specific problems tend to improve the most.

Culture, Gender, and Values in Psychotherapy

72-5 How do culture, gender, and values influence the therapist-client relationship?

All therapies offer hope, and nearly all therapists attempt to enhance their clients' sensitivity, openness, personal responsibility, and sense of purpose (Jensen & Bergin, 1988). But in matters of diversity, therapists differ from one another and may differ from their clients (Delaney et al., 2007; Kelly, 1990).

These differences can become significant when a therapist from one culture or gender meets a client from another. In North America, Europe, and Australia, for example, most therapists reflect their culture's individualism, which often gives priority to personal desires and identity, particularly for men. Clients who are immigrants from Asian countries, where people are mindful of others' expectations, may have trouble relating to therapies that require them to think only of their own well-being. And women seeking therapy who are from a collectivist culture might be doubly discomfited. Such differences help explain minority populations' reluctance to use mental health services and their tendency to prematurely terminate therapy (Chen et al., 2009; Sue, 2006). In one experiment, Asian-American clients matched with counselors who shared their cultural values (rather than mismatched with those who did not) perceived more counselor empathy and felt a stronger alliance with the counselor (Kim et al., 2005). Recognizing that therapists and clients may differ in their values, communication styles, and language, American Psychological Association-accredited therapy training programs now provide training in cultural sensitivity and recruit members of underrepresented cultural groups.

Another area of potential conflict related to values is religion. Highly religious people may prefer and benefit from religiously similar therapists (Masters, 2010; Smith et al., 2007; Wade et al., 2006). They may have trouble establishing an emotional bond with a therapist who does not share their values.

David Bufington/Getty Images

A caring relationship Effective therapists form a bond of trust with their clients.

therapeutic alliance a bond of trust and mutual understanding between a therapist and client, who work together constructively to overcome the client's problem.

Albert Ellis, who advocated the aggressive rational-emotive behavior therapy (REBT), and Allen Bergin, co-editor of the *Handbook of Psychotherapy and Behavior Change*, illustrated how sharply therapists can differ, and how those differences can affect their view of a healthy person. Ellis (1980) assumed that “no one and nothing is supreme,” that “self-gratification” should be encouraged, and that “unequivocal love, commitment, service, and . . . fidelity to any interpersonal commitment, especially marriage, leads to harmful consequences.” Bergin (1980) assumed the opposite—that “because God is supreme, humility and the acceptance of divine authority are virtues,” that “self-control and committed love and self-sacrifice are to be encouraged,” and that “infidelity to any interpersonal commitment, especially marriage, leads to harmful consequences.”

Bergin and Ellis disagreed more radically than most therapists on what values are healthiest. In so doing, however, they agreed on a more general point: Psychotherapists’ personal beliefs influence their practice. Because clients tend to adopt their therapists’ values (Worthington et al., 1996), some psychologists believe therapists should divulge those values more openly. (For those thinking about seeking therapy, *Close-up: A Consumer’s Guide to Psychotherapists* offers some tips on when to seek help and how to start searching for a therapist who shares your perspective and goals.)

Close-up

A Consumer’s Guide to Psychotherapists

72-6

What should a person look for when selecting a therapist?

Life for everyone is marked by a mix of serenity and stress, blessing and bereavement, good moods and bad. So, when should we seek a mental health professional’s help? The American Psychological Association offers these common trouble signals:

- Feelings of hopelessness
- Deep and lasting depression
- Self-destructive behavior, such as substance use disorder
- Disruptive fears

- Sudden mood shifts
- Thoughts of suicide
- Compulsive rituals, such as hand washing
- Hearing voices or seeing things that others don’t experience

In looking for a therapist, you may want to have a preliminary consultation with two or three. High school counseling offices are generally good starting points, and may offer some free services. You can describe your problem and learn each therapist’s treatment approach. You can ask questions about the therapist’s values, credentials (**TABLE 72.1**), and fees. And you can assess your own feelings about each of them. The emotional bond between therapist and client is perhaps the most important factor in effective therapy.

TABLE 72.1

Therapists and Their Training

Type	Description
<i>Clinical psychologists</i>	Most are psychologists with a Ph.D. (includes research training) or Psy.D. (focuses on therapy) supplemented by a supervised internship and, often, postdoctoral training. About half work in agencies and institutions, half in private practice.
<i>Psychiatrists</i>	Psychiatrists are physicians who specialize in the treatment of psychological disorders. Not all psychiatrists have had extensive training in psychotherapy, but as M.D.s or D.O.s they can prescribe medications. Thus, they tend to see those with the most serious problems. Many have their own private practice.
<i>Clinical or psychiatric social workers</i>	A two-year master of social work graduate program plus postgraduate supervision prepares some social workers to offer psychotherapy, mostly to people with everyday personal and family problems. About half have earned the National Association of Social Workers’ designation of clinical social worker.
<i>Counselors</i>	Marriage and family counselors specialize in problems arising from family relations. Clergy provide counseling to countless people. Abuse counselors work with substance abusers and with spouse and child abusers and their victims. Mental health and other counselors may be required to have a two-year master’s degree.

Preventing Psychological Disorders

72-7 What is the rationale for preventive mental health programs?

We have seen that lifestyle change can help *reverse* some of the symptoms of psychological disorders. Might such change also *prevent* some disorders by building individuals' **resilience**—an ability to cope with stress and recover from adversity? Faced with unforeseen trauma, most adults exhibit resilience. This was true of New Yorkers in the aftermath of the September 11 terrorist attacks, especially those who enjoyed supportive close relationships and who had not recently experienced other stressful events (Bonanno et al., 2007). More than 9 in 10 New Yorkers, although stunned and grief-stricken by 9/11, did *not* have a dysfunctional stress reaction. By the following January, the stress symptoms of those who did were mostly gone (Person et al., 2006). Even in groups of combat-stressed veterans and political rebels who have survived dozens of episodes of torture, most do not later exhibit posttraumatic stress disorder (Mineka & Zinbarg, 1996).

Psychotherapies and biomedical therapies tend to locate the cause of psychological disorders within the person with the disorder. We infer that people who act cruelly must be cruel and that people who act “crazy” must be “sick.” We attach labels to such people, thereby distinguishing them from “normal” folks. It follows, then, that we try to treat “abnormal” people by giving them insight into their problems, by changing their thinking, by helping them gain control with drugs.

There is an alternative viewpoint: We could interpret many psychological disorders as understandable responses to a disturbing and stressful society. According to this view, it is not just the person who needs treatment, but also the person's social context. Better to prevent a problem by reforming a sick situation and by developing people's coping competencies than to wait for a problem to arise and then treat it.

A story about the rescue of a drowning person from a rushing river illustrates this viewpoint: Having successfully administered first aid to the first victim, the rescuer spots another struggling person and pulls her out, too. After a half-dozen repetitions, the rescuer suddenly turns and starts running away while the river sweeps yet another floundering person into view. “Aren't you going to rescue that fellow?” asks a bystander. “Heck no,” the rescuer replies. “I'm going upstream to find out what's pushing all these people in.”

Preventive mental health is upstream work. It seeks to prevent psychological casualties by identifying and alleviating the conditions that cause them. As George Albee (1986) pointed out, there is abundant evidence that poverty, meaningless work, constant criticism, unemployment, racism, sexism, and heterosexism undermine people's sense of competence, personal control, and self-esteem. Such stresses increase their risk of depression, alcohol use disorder, and suicide.

We who care about preventing psychological casualties should, Albee contended, support programs that alleviate these demoralizing situations. We eliminated smallpox not by treating the afflicted but by inoculating the unafflicted. We conquered yellow fever by controlling mosquitoes. Preventing psychological problems means empowering those who feel helpless, changing environments that breed loneliness, renewing the disintegrating family, promoting communication training for couples, and bolstering parents' and teachers' skills. “Everything aimed at improving the human condition, at making life more fulfilling and meaningful, may be considered part of primary prevention of mental or emotional disturbance” (Kessler & Albee, 1975, p. 557). That includes the cognitive training that promotes positive thinking in children at risk for depression (Brunwasser et al., 2009; Gillham et al., 2006; Stice et al., 2009). A 2009 National Research Council and Institute of Medicine report—*Preventing Mental, Emotional, and Behavioral Disorders Among Young People*—offers encouragement. It documents that intervention efforts often based on cognitive-behavioral therapy principles significantly boost child and adolescent flourishing. Through such preventive efforts and healthy lifestyles, fewer of us will fall into the rushing river of psychological disorders.

resilience the personal strength that helps most people cope with stress and recover from adversity and even trauma.

“It is better to prevent than to cure.” -PERUVIAN FOLK WISDOM

“Mental disorders arise from physical ones, and likewise physical disorders arise from mental ones.” -THE MAHABHARATA, 200 B.C.E.

Before You Move On

▶ ASK YOURSELF

Can you think of a specific way that improving the environment in your own community might prevent some psychological disorders among its residents?

▶ TEST YOURSELF

What is the difference between preventive mental health and psychological or biomedical therapy?

Answers to the Test Yourself questions can be found in Appendix E at the end of the book.

Module 72 Review

72-1 Does psychotherapy work? Who decides?

- Clients' and therapists' positive testimonials cannot prove that therapy is actually effective, and the placebo effect and *regression toward the mean* (the tendency for extreme or unusual scores to fall back toward their average) make it difficult to judge whether improvement occurred because of the treatment.
- Using *meta-analyses* to statistically combine the results of hundreds of randomized psychotherapy outcome studies, researchers have found that those not undergoing treatment often improve, but those undergoing psychotherapy are more likely to improve more quickly, and with less chance of relapse.

72-2 Are some psychotherapies more effective than others for specific disorders?

- No one type of psychotherapy is generally superior to all others. Therapy is most effective for those with clear-cut, specific problems.
- Some therapies—such as behavior conditioning for treating phobias and compulsions—are more effective for specific disorders.
- Psychodynamic therapy helped treat depression and anxiety, and cognitive and cognitive-behavioral therapies have been effective in coping with anxiety, obsessive-compulsive disorder, posttraumatic stress disorder, and depression.
- *Evidence-based practice* integrates the best available research with clinicians' expertise and patients' characteristics, preferences, and circumstances.

72-3 How do alternative therapies fare under scientific scrutiny?

- Controlled research has found some benefits of eye movement desensitization and reprocessing (EMDR) therapy for PTSD, though possibly for reasons unrelated to eye movements.
- Light exposure therapy does seem to relieve depression symptoms for those with a seasonal pattern of major depressive disorder by activating a brain region that influences arousal and hormones.

72-4 What three elements are shared by all forms of psychotherapy?

- All psychotherapies offer new hope for demoralized people; a fresh perspective; and (if the therapist is effective) an empathic, trusting, and caring relationship.
- The emotional bond of trust and understanding between therapist and client—the *therapeutic alliance*—is an important element in effective therapy.

72-5 How do culture, gender, and values influence the therapist-client relationship?

- Therapists differ in the values that influence their goals in therapy and their views of progress. These differences may create problems if therapists and clients differ in their cultural, gender, or religious perspectives.

72-6 What should a person look for when selecting a therapist?

- A person seeking therapy may want to ask about the therapist's treatment approach, values, credentials, and fees.
- An important consideration is whether the therapy seeker feels comfortable and able to establish a bond with the therapist.

72-7 What is the rationale for preventive mental health programs?

- Preventive mental health programs are based on the idea that many psychological disorders could be prevented by changing oppressive, esteem-destroying environments into more benevolent, nurturing environments that foster growth, self-confidence, and *resilience*.

Multiple-Choice Questions

1. Which of the following does the text's author call psychology's most powerful tool for sorting reality from wishful thinking?
 - a. ESP or "psychic powers"
 - b. Regression toward the mean
 - c. Client perception
 - d. Control group
 - e. Placebo effect
2. Which of the following best describes meta-analysis?
 - a. Evidenced-based practice
 - b. A treatment versus no treatment group
 - c. A tendency for smaller scores to move toward the average
 - d. Regressing from unusual to usual
 - e. A way to combine the results of lots of studies
3. Which of the following is the best phrase for a bond of trust and mutual understanding between a therapist and client who are working to overcome the client's problem?
 - a. Therapeutic alliance
 - b. EMDR
 - c. Evidence-based practice
 - d. Meta-analysis
 - e. Outcome research

Practice FRQs

1. Explain the three sides of evidence-based clinical decision making.

Answer

1 point: Using the best available research evidence.

1 point: Clinical expertise.

1 point: Using a patient's values, preferences, and circumstances.

2. Psychotherapies have many common ingredients. Identify three commonly agreed-upon benefits of psychotherapies.

(3 points)

Module 73

The Biomedical Therapies

Module Learning Objectives

- 73-1** Identify and describe the drug therapies, and explain how double-blind studies help researchers evaluate a drug's effectiveness.
- 73-2** Describe the use of brain stimulation techniques and psychosurgery in treating specific disorders.
- 73-3** Describe how, by taking care of themselves with a healthy lifestyle, people might find some relief from depression, and explain how this reflects our being biopsychosocial systems.

TANNEN MAURY/Landov

psychopharmacology the study of the effects of drugs on mind and behavior.

Drug or placebo effect? For many people, depression lifts while taking an antidepressant drug. But people given a placebo may experience the same effect. Double-blind clinical trials suggest that, especially for those with severe depression, antidepressant drugs do have at least a modest clinical effect.

© The New Yorker Collection, 2007. Edward Koren from cartoonbank.com. All Rights Reserved.

"Our psychopharmacologist is a genius."

Psychotherapy is one way to treat psychological disorders. The other, often used with serious disorders, is biomedical therapy—physically changing the brain's functioning by altering its chemistry with drugs, or affecting its circuitry with electroconvulsive shock, magnetic impulses, or psychosurgery. Primary care providers prescribe most drugs for anxiety and depression, followed by psychiatrists and, in some states, psychologists.

Drug Therapies

- 73-1** What are the drug therapies? How do double-blind studies help researchers evaluate a drug's effectiveness?

By far the most widely used biomedical treatments today are the drug therapies. Since the 1950s, discoveries in **psychopharmacology** (the study of drug effects on mind and behavior) have revolutionized the treatment of people with severe disorders, liberating hundreds of thousands from hospital confinement. Thanks to drug therapy—and to efforts to minimize involuntary hospitalization and to support people through community mental health programs—the resident population of mental hospitals is a small fraction of what it was a half-century ago. For some unable to care for themselves, however, release from hospitals has meant homelessness, not liberation.

Almost any new treatment, including drug therapy, is greeted by an initial wave of enthusiasm as many people apparently improve. But that enthusiasm often diminishes after researchers subtract the rates of (1) normal recovery among untreated persons and (2) recovery due to the placebo effect, which arises from the positive expectations of patients and mental health workers alike. So, to evaluate the effectiveness of any new drug, researchers give half the patients the drug, and the other half a similar-appearing placebo. Because neither the staff nor the patients know who gets which, this is called a *double-blind procedure*. The good news: In double-blind studies, some drugs have proven useful.

Antipsychotic Drugs

The revolution in drug therapy for psychological disorders began with the accidental discovery that certain drugs, used for other medical purposes, calmed patients with *psychoses* (disorders in which hallucinations or delusions indicate some loss of contact with reality). These **antipsychotic drugs**, such as chlorpromazine (sold as Thorazine), dampened responsiveness to irrelevant stimuli. Thus, they provided the most help to patients experiencing positive symptoms of schizophrenia, such as auditory hallucinations and paranoia (Lehman et al., 1998; Lenzenweger et al., 1989).

The molecules of most conventional antipsychotic drugs are antagonists; they are similar enough to molecules of the neurotransmitter dopamine to occupy its receptor sites and block its activity. This finding reinforces the idea that an overactive dopamine system contributes to schizophrenia.

Antipsychotics also have powerful side effects. Some produce sluggishness, tremors, and twitches similar to those of Parkinson's disease (Kaplan & Saddock, 1989). Long-term use of antipsychotics can produce *tardive dyskinesia*, with involuntary movements of the facial muscles (such as grimacing), tongue, and limbs. Although not more effective in controlling schizophrenia symptoms, many of the newer-generation antipsychotics, such as risperidone (Risperdal) and olanzapine (Zyprexa), have fewer of these effects. These drugs may, however, increase the risk of obesity and diabetes (Buchanan et al., 2010; Tiihonen et al., 2009).

Antipsychotics, combined with life-skills programs and family support, have given new hope to many people with schizophrenia (Guo, 2010). Hundreds of thousands of patients have left the wards of mental hospitals and returned to work and to near-normal lives (Leucht et al., 2003).

Antianxiety Drugs

Like alcohol, **antianxiety drugs**, such as Xanax or Ativan, depress central nervous system activity (and so should not be used in combination with alcohol). Antianxiety drugs are often used in combination with psychological therapy. One antianxiety drug, the antibiotic D-cycloserine, acts upon a receptor that, in combination with behavioral treatments, facilitates the extinction of learned fears. Experiments indicate that the drug enhances the benefits of exposure therapy and helps relieve the symptoms of posttraumatic stress disorder and obsessive-compulsive disorder (Davis, 2005; Kushner et al., 2007).

A criticism sometimes made of the behavior therapies—that they reduce symptoms without resolving underlying problems—is also made of drug therapies. Unlike the behavior therapies, however, these substances may be used as an ongoing treatment. “Popping a Xanax” at the first sign of tension can create a learned response; the immediate relief reinforces a person's tendency to take drugs when anxious. Antianxiety drugs can also be addicting. After heavy use, people who stop taking them may experience increased anxiety, insomnia, and other withdrawal symptoms.

Over the dozen years at the end of the twentieth century, the rate of outpatient treatment for anxiety disorders, obsessive-compulsive disorder, and posttraumatic stress disorder nearly doubled. The proportion of psychiatric patients receiving medication during that time increased from 52 to 70 percent (Olfson et al., 2004). And the new standard drug treatment for anxiety disorders? Antidepressants.

Antidepressant Drugs

The **antidepressants** were named for their ability to lift people up from a state of depression, and this was their main use until recently. The label is a bit of a misnomer now that these drugs are increasingly being used to successfully treat anxiety disorders, obsessive-compulsive disorder, and posttraumatic stress disorder. These drugs are agonists; they work by increasing the availability of certain neurotransmitters, such as norepinephrine or serotonin, which

AP® Exam Tip

The discussion of drug therapies is a great opportunity for you to review information about neurotransmitters and brain function. See Unit III if you need to brush up on these topics.

FYI

Perhaps you can guess an occasional side effect of L-dopa, a drug that raises dopamine levels for Parkinson's patients: hallucinations.

antipsychotic drugs drugs used to treat schizophrenia and other forms of severe thought disorder.

antianxiety drugs drugs used to control anxiety and agitation.

antidepressant drugs drugs used to treat depression, anxiety disorders, obsessive-compulsive disorder, and posttraumatic stress disorder. (Several widely used antidepressant drugs are *selective serotonin reuptake inhibitors*—SSRIs.)

© John Greim/Age fotostock

elevate arousal and mood and appear scarce when a person experiences feelings of depression or anxiety. Fluoxetine, which tens of millions of users worldwide have known as Prozac, falls into this category of drugs. The most commonly prescribed drugs in this group, including Prozac and its cousins Zoloft and Paxil, work by blocking the reabsorption and removal of serotonin from synapses (**FIGURE 73.1**). Given their use in treating disorders other than depression—from anxiety to strokes—this group of drugs is most often called *SSRIs* (*selective serotonin reuptake inhibitors*) rather than antidepressants (Kramer, 2011). Some of the older antidepressant drugs work by blocking the reabsorption or breakdown of both norepinephrine and serotonin. Though effective, these dual-action drugs have more potential side effects, such as dry mouth, weight gain, hypertension, or dizzy spells (Anderson, 2000; Mulrow, 1999). Administering them by means of a patch, bypassing the intestines and liver, helps reduce such side effects (Bodkin & Amsterdam, 2002).

After the introduction of SSRI drugs, the percentage of patients receiving medication for depression jumped dramatically, from 70 percent in 1987, the year before SSRIs were introduced, to 89 percent in 2001 (Olfson et al., 2003; Stafford et al., 2001). From 1996 to 2005, the number of Americans prescribed antidepressant drugs doubled, from 13 to 27 million (Olfson & Marcus, 2009). Between 2002 and 2007 in Australia, antidepressant drug use increased 41 percent (Hollingworth et al., 2010).

Be advised: Patients with depression who begin taking antidepressants do not wake up the next day singing “It’s a beautiful day”! Although the drugs begin to influence neurotransmission within hours, their full psychological effect often requires four weeks. One possible reason for the delay is that increased serotonin promotes *neurogenesis*—the birth of new brain cells, perhaps reversing stress-induced loss of neurons (Becker & Wojtowicz, 2007; Jacobs, 2004).

Antidepressant drugs are not the only way to give the body a lift. Aerobic exercise, which calms people who feel anxious and energizes those who feel depressed, does about as much good for some people with mild to moderate depression, and has additional positive side effects (more on this topic later in this module). Cognitive therapy, by helping people reverse their habitual negative thinking style, can boost the drug-aided relief from depression and reduce the post-treatment risk of relapse (Hollon et al., 2002; Keller et al., 2000; Vittengl et al., 2007). Better yet, some studies suggest, is to attack depression (and anxiety) from both below and above (Cuijpers et al., 2010; Walkup et al., 2008). Use antidepressant drugs (which work, bottom-up, on the emotion-forming limbic system) in conjunction with cognitive-behavioral therapy (which works top-down, starting with changed frontal lobe activity).

Figure 73.1

Biology of antidepressants

Shown here is the action of Prozac, which partially blocks the reuptake of serotonin.

Researchers generally agree that people with depression often improve after a month on antidepressants. But after allowing for natural recovery and the placebo effect, how big is the drug effect? Not big, report Irving Kirsch and his colleagues (1998, 2002, 2010). Their analyses of double-blind clinical trials indicate that the placebo effect accounted for about 75 percent of the active drug's effect. In a follow-up review that included unpublished clinical trials, the antidepressant drug effect was again modest (Kirsch et al., 2008). The placebo effect was less for those with severe depression, which made the added benefit of the drug somewhat greater for them. "Given these results, there seems little reason to prescribe antidepressant medication to any but the most severely depressed patients, unless alternative treatments have failed," Kirsch concluded (BBC, 2008). A newer analysis confirms that the antidepressant benefit compared with placebos is "minimal or nonexistent, on average, in patients with mild or moderate symptoms." For those folks, aerobic exercise or psychotherapy is often effective. But among patients with "very severe" depression, the medication advantage becomes "substantial" (Fournier et al., 2010).

"If this doesn't help you don't worry, it's a placebo."

"No twisted thought without a twisted molecule." -ATTRIBUTED TO PSYCHOLOGIST RALPH GERARD

Mood-Stabilizing Medications

In addition to antipsychotic, antianxiety, and antidepressant drugs, psychiatrists have *mood-stabilizing drugs* in their arsenal. For those suffering the emotional highs and lows of bipolar disorder, the simple salt *lithium* can be an effective mood stabilizer. Australian physician John Cade discovered this in the 1940s when he administered lithium to a patient with severe mania and the patient became perfectly well in less than a week (Snyder, 1986). After suffering mood swings for years, about 7 in 10 people with bipolar disorder benefit from a long-term daily dose of this cheap salt, which helps prevent or ease manic episodes and, to a lesser extent, lifts depression (Solomon et al., 1995). It also protects neural health, thus reducing bipolar patients' vulnerability to significant cognitive decline (Kessing et al., 2010).

Lithium also reduces bipolar patients' risk of suicide—to about one-sixth of bipolar patients not taking lithium (Tondo et al., 1997). Lithium amounts in drinking water have also correlated with lower suicide rates (across 18 Japanese cities and towns) and lower crime rates (across 27 Texas counties) (Ohgami et al., 2009; Schrauzer & Shrestha, 1990, 2010; Terao et al., 2010). Although we do not fully understand why, lithium works. And so does Depakote, a drug originally used to treat epilepsy and more recently found effective in the control of manic episodes associated with bipolar disorder.

"Lithium prevents my seductive but disastrous highs, diminishes my depressions, clears out the wool and webbing from my disordered thinking, slows me down, gentles me out, keeps me from ruining my career and relationships, keeps me out of a hospital, alive, and makes psychotherapy possible."
-KAY REDFIELD JAMISON, *AN UNQUIET MIND*, 1995

Brain Stimulation

73-2

How are brain stimulation and psychosurgery used in treating specific disorders?

Electroconvulsive Therapy

A more controversial brain manipulation occurs through shock treatment, or **electroconvulsive therapy (ECT)**. When ECT was first introduced in 1938, the wide-awake patient was strapped to a table and jolted with roughly 100 volts of electricity to the brain, producing racking convulsions and brief unconsciousness. ECT therefore gained a barbaric image, one that lingers. Today, however, the patient receives a general anesthetic and a muscle relaxant (to prevent injury from seizures) before a psychiatrist delivers 30 to 60 seconds of electrical current (**FIGURE 73.2** on the next page). Within 30 minutes, the patient awakens and remembers nothing of the treatment or of the preceding hours. After three such sessions each week for two to four weeks, 80 percent or more of people receiving ECT improve markedly, showing some memory loss for the treatment period but no discernible brain damage.

electroconvulsive therapy (ECT)

a biomedical therapy for severely depressed patients in which a brief electric current is sent through the brain of an anesthetized patient.

FYI

The medical use of electricity is an ancient practice. Physicians treated the Roman Emperor Claudius (10 B.C.E.–54 C.E.) for headaches by pressing electric eels to his temples.

Figure 73.2**Electroconvulsive therapy**

Although controversial, ECT is often an effective treatment for depression that does not respond to drug therapy. “Electroconvulsive” is no longer accurate because patients are now given a drug that prevents injurious seizures.

Rick Friedman/Corbis

ECT proponent In her book, *Shock: The Healing Power of Electroconvulsive Therapy* (2006), Kitty Dukakis writes, “I used to . . . be unable to shake the dread even when I was feeling good, because I knew the bad feelings would return. ECT has wiped away that foreboding. It has given me a sense of control, of hope.”

Study after study confirms that ECT is an effective treatment for severe depression in “treatment-resistant” patients who have not responded to drug therapy (Bailine et al., 2010; Fink, 2009; UK ECT Review Group, 2003). An editorial in the *Journal of the American Medical Association* concluded that “the results of ECT in treating severe depression are among the most positive treatment effects in all of medicine” (Glass, 2001).

How does ECT alleviate severe depression? After more than 70 years, no one knows for sure. One recipient likened ECT to the smallpox vaccine, which was saving lives before we knew how it worked. Others think of it as rebooting their cerebral computer. But what makes it therapeutic? Perhaps the shock-induced seizures calm neural centers where overactivity produces depression. ECT, like antidepressant drugs and exercise, also appears to boost the production of new brain cells (Bolwig & Madsen, 2007).

Skeptics have raised one other possible explanation for how ECT works: as a placebo effect. Most ECT studies have failed to contain a control condition in which people are randomly assigned to receive the same general anesthesia and simulated ECT without the shock. When given this placebo treatment, note John Read and Richard Bentall (2010), the positive expectation is therapeutic, though a Food and Drug Administration (2011) research review concludes that ECT is more effective than a placebo, especially in the short run.

ECT is now administered with briefer pulses, sometimes only to the brain’s right side and with less memory disruption (HMHL, 2007). Yet no matter how impressive the results, the idea of electrically shocking people still strikes many as barbaric, especially given our ignorance about why ECT works. Moreover, about 4 in 10 ECT-treated patients relapse into depression within six months (Kellner et al., 2006). Nevertheless, in the minds of many psychiatrists and patients, ECT is a lesser evil than severe depression’s misery, anguish, and risk of suicide. As research psychologist Norman Endler (1982) reported after ECT alleviated his deep depression, “A miracle had happened in two weeks.”

Alternative Neurostimulation Therapies

Two other neural stimulation techniques—magnetic stimulation and deep-brain stimulation—are raising hopes for gentler alternatives that jump-start neural circuits in the depressed brain.

MAGNETIC STIMULATION

Depressed moods seem to improve when repeated pulses surge through a magnetic coil held close to a person's skull (**FIGURE 73.3**). The painless procedure—called **repetitive transcranial magnetic stimulation (rTMS)**—is performed on wide-awake patients over several weeks. Unlike ECT, the rTMS procedure produces no seizures, memory loss, or other serious side effects. (Headaches can result.)

Initial studies have found “modest” positive benefits of rTMS (Daskalakis et al., 2008; George et al., 2010; López-Ibor et al., 2008). How it works is unclear. One possible explanation is that the stimulation energizes the brain's left frontal lobe, which is relatively inactive during depression (Helmuth, 2001). Repeated stimulation may cause nerve cells to form new functioning circuits through the process of long-term potentiation. (See Module 32 for more details on long-term potentiation.)

repetitive transcranial magnetic stimulation (rTMS) the application of repeated pulses of magnetic energy to the brain; used to stimulate or suppress brain activity.

FYI

A meta-analysis of 17 clinical experiments found that one other stimulation procedure alleviates depression: massage therapy (Hou et al., 2010).

Figure 73.3

Magnets for the mind Repetitive transcranial magnetic stimulation (rTMS) sends a painless magnetic field through the skull to the surface of the cortex. Pulses can be used to stimulate or dampen activity in various cortical areas. (From George, 2003.)

DEEP-BRAIN STIMULATION

Other patients whose depression has resisted both drugs that flood the body and ECT that jolts at least half the brain have benefited from an experimental treatment pinpointed at a depression center in the brain. Neuroscientist Helen Mayberg and her colleagues (2005, 2006, 2007, 2009) have been focusing on a neural hub that bridges the thinking frontal lobes to the limbic system. This area, which is overactive in the brain of a depressed or temporarily sad person, calms when treated by ECT or antidepressants. To experimentally excite neurons that inhibit this negative emotion-feeding activity, Mayberg drew upon the deep-brain stimulation technology sometimes used to treat Parkinson's tremors. Among an initial 20 patients receiving implanted electrodes and a pacemaker stimulator, 12 experienced relief, which was sustained over three to six years of follow-up (Kennedy et al., 2011).

A depression switch?

By comparing the brains of patients with and without depression, researcher Helen Mayberg identified a brain area that appears active in people who are depressed or sad, and whose activity may be calmed by deep-brain stimulation.

© Erik S. Lesser

psychosurgery surgery that removes or destroys brain tissue in an effort to change behavior.

lobotomy a psychosurgical procedure once used to calm uncontrollably emotional or violent patients. The procedure cut the nerves connecting the frontal lobes to the emotion-controlling centers of the inner brain.

Some felt suddenly more aware and became more talkative and engaged; others improved only slightly if at all. Future research will explore whether Mayberg has discovered a switch that can lift depression. Other researchers are following up on reports that deep-brain stimulation can offer relief to people with obsessive-compulsive disorder (Rabins et al., 2009).

Psychosurgery

Because its effects are irreversible, **psychosurgery**—surgery that removes or destroys brain tissue—is the most drastic and the least-used biomedical intervention for changing behavior. In the 1930s, Portuguese physician Egas Moniz developed what became the best-known psychosurgical operation: the **lobotomy**. Moniz found that cutting the nerves connecting the frontal lobes with the emotion-controlling centers of the inner brain calmed uncontrollably emotional and violent patients. In what would later become a crude but easy and inexpensive procedure that took only about 10 minutes, a neurosurgeon would shock the patient into a coma, hammer an icepick-like instrument through each eye socket into the brain, and then wiggle it to sever connections running up to the frontal lobes. Between 1936 and 1954, tens of thousands of severely disturbed people were “lobotomized” (Valenstein, 1986).

Although the intention was simply to disconnect emotion from thought, a lobotomy’s effect was often more drastic: It usually decreased the person’s misery or tension, but also produced a permanently lethargic, immature, uncreative person. During the 1950s, after some 35,000 people had been lobotomized in the United States alone, calming drugs became available and psychosurgery was largely abandoned. Today, lobotomies are history. But more precise, microscale psychosurgery is sometimes used in extreme cases. For example, if a patient suffers uncontrollable seizures, surgeons can deactivate the specific nerve clusters that cause or transmit the convulsions. MRI-guided precision surgery is also occasionally done to cut the circuits involved in severe obsessive-compulsive disorder (Carey, 2009, 2011; Sachdev & Sachdev, 1997). Because these procedures are irreversible, they are controversial and neurosurgeons perform them only as a last resort.

Therapeutic Lifestyle Change

73-3

How, by taking care of themselves with a healthy lifestyle, might people find some relief from depression, and how does this reflect our being biopsychosocial systems?

The effectiveness of the biomedical therapies reminds us of a fundamental lesson: We find it convenient to talk of separate psychological and biological influences, but everything psychological is also biological (**FIGURE 73.4**). Every thought and feeling depends on the

Failed lobotomy This 1940 photo shows Rosemary Kennedy (center) at age 22 with brother (and future U.S. president) John and sister Jean. A year later her father, on medical advice, approved a lobotomy that was promised to control her reportedly violent mood swings. The procedure left her confined to a hospital with an infantile mentality until her death in 2005 at age 86.

New York Times Co./Getty Images

functioning brain. Every creative idea, every moment of joy or anger, every period of depression emerges from the electrochemical activity of the living brain. The influence is two-way: When psychotherapy relieves obsessive-compulsive behavior, PET scans reveal a calmer brain (Schwartz et al., 1996).

Anxiety disorders, obsessive-compulsive disorder, posttraumatic stress disorder, major depression, bipolar disorder, and schizophrenia are all biological events. As we have seen over and over again, *a human being is an integrated biopsychosocial system*. For years, we have considered the health of our bodies and minds separately. That neat separation no longer seems valid. Stress affects body chemistry and health. And chemical imbalances, whatever their cause, can produce schizophrenia, depression, and other mental disorders.

That lesson is being applied by Stephen Ilardi (2009) in training seminars promoting *therapeutic lifestyle change*. Human brains and bodies were designed for physical activity and social engagement, they note. Our ancestors hunted, gathered, and built in groups, with little evidence of disabling depression. Indeed, those whose way of life entails strenuous physical activity, strong community ties, sunlight exposure, and plenty of sleep (think of foraging bands in Papua New Guinea, or Amish farming communities in North America) rarely experience depression. For both children and adults, outdoor activity in natural environments—perhaps a walk in the woods—reduces stress and promotes health (NEEF, 2011; Phillips, 2011). “Simply put: humans were never designed for the sedentary, disengaged, socially isolated, poorly nourished, sleep-deprived pace of twenty-first-century American life.”

The Ilardi team was also impressed by research showing that regular aerobic exercise and a complete night’s sleep boost mood and energy. So they invited small groups of people with depression to undergo a 12-week training program with the following goals:

- *Aerobic exercise*, 30 minutes a day, at least 3 times weekly (increasing fitness and vitality, stimulating endorphins)
- *Adequate sleep*, with a goal of 7 to 8 hours a night (increasing energy and alertness, boosting immunity)
- *Light exposure*, at least 30 minutes each morning with a light box (amplifying arousal, influencing hormones)
- *Social connection*, with less alone time and at least two meaningful social engagements weekly (satisfying the human need to belong)
- *Antirumination*, by identifying and redirecting negative thoughts (enhancing positive thinking)
- *Nutritional supplements*, including a daily fish oil supplement with omega-3 fatty acids (supporting healthy brain functioning)

In one study of 74 people, 77 percent of those who completed the program experienced relief from depressive symptoms, compared with 19 percent in those assigned to a treatment-as-usual control condition. Future research will seek to replicate this striking result of lifestyle change, and also to identify which of the treatment components (additively or in some combination) produce the therapeutic effect. In the meantime, there seems little reason to doubt the truth of the Latin adage, *Mens sana in corpore sano*: “A healthy mind in a healthy body.”

TABLE 73.1 on the next page summarizes some aspects of the biomedical therapies we’ve discussed.

Figure 73.4

Mind-body interaction The biomedical therapies assume that mind and body are a unit: Affect one and you will affect the other.

sturti/Getty Images

Healthier lifestyles Researchers suggest that therapeutic lifestyle change can be an effective antidote for people with depression. The changes include managing sleep time, spending more time outdoors (or with a light box), getting more exercise, and developing more social connections.

Table 73.1 Comparing Biomedical Therapies

Therapy	Presumed Problem	Therapy Aim	Therapy Technique
<i>Drug therapies</i>	Neurotransmitter malfunction	Control symptoms of psychological disorders.	Alter brain chemistry through drugs.
<i>Brain stimulation</i>	Severe, “treatment-resistant” depression	Alleviate depression that is unresponsive to drug therapy.	Stimulate brain through electroconvulsive shock, magnetic impulses, or deep-brain stimulation.
<i>Psychosurgery</i>	Brain malfunction	Relieve severe disorders.	Remove or destroy brain tissue.
<i>Therapeutic lifestyle change</i>	Stress and unhealthy lifestyle	Restore healthy biological state.	Alter lifestyle through adequate exercise, sleep, and other changes.

Before You Move On

▶ ASK YOURSELF

If a troubled friend asked, how would you summarize the available biomedical therapies?

▶ TEST YOURSELF

How do researchers evaluate the effectiveness of particular drug therapies?

Answers to the Test Yourself questions can be found in Appendix E at the end of the book.

Module 73 Review

73-1

What are the drug therapies? How do double-blind studies help researchers evaluate a drug’s effectiveness?

- *Psychopharmacology*, the study of drug effects on mind and behavior, has helped make drug therapy the most widely used biomedical therapy.
- *Antipsychotic drugs*, used in treating schizophrenia, block dopamine activity. Side effects may include tardive dyskinesia (with involuntary movements of facial muscles, tongue, and limbs) or increased risk of obesity and diabetes.
- *Antianxiety drugs*, which depress central nervous system activity, are used to treat anxiety disorders, obsessive-compulsive disorder, and posttraumatic stress disorder. These drugs can be physically and psychologically addictive.
- *Antidepressant drugs*, which increase the availability of serotonin and norepinephrine, are used for depression, with modest effectiveness beyond that of placebo drugs. The antidepressants known as selective serotonin reuptake inhibitors (SSRIs) are now used to treat other disorders, including strokes, anxiety disorders, obsessive-compulsive disorder, and posttraumatic stress disorder.
- Lithium and Depakote are mood stabilizers prescribed for those with bipolar disorder.
- Studies may use a double-blind procedure to avoid the placebo effect and researchers’ bias.

73-2

How are brain stimulation and psychosurgery used in treating specific disorders?

- *Electroconvulsive therapy (ECT)*, in which a brief electric current is sent through the brain of an anesthetized patient, is an effective treatment for severely depressed people who have not responded to other therapy.
- Newer alternative treatments for depression include *repetitive transcranial magnetic stimulation (rTMS)* and, in preliminary clinical experiments, deep-brain stimulation that calms an overactive brain region linked with negative emotions.
- *Psychosurgery* removes or destroys brain tissue in hopes of modifying behavior.
 - Radical psychosurgical procedures such as the *lobotomy* were once popular, but neurosurgeons now rarely perform brain surgery to change behavior or moods.
 - Brain surgery is a last-resort treatment because its effects are irreversible.

73-3

How, by taking care of themselves with a healthy lifestyle, might people find some relief from depression, and how does this reflect our being biopsychosocial systems?

- Depressed people who undergo a program of aerobic exercise, adequate sleep, light exposure, social engagement, negative-thought reduction, and better nutrition often gain some relief.
- In our integrated biopsychosocial system, stress affects our body chemistry and health; chemical imbalances can produce depression; and social support and other lifestyle changes can lead to relief of symptoms.

Multiple-Choice Questions

1. Which neurotransmitter is affected by antipsychotic medications?
 - a. Epinephrine
 - b. Dopamine
 - c. Norepinephrine
 - d. Acetylcholine
 - e. Serotonin
2. Which of the following is most effectively treated with electroconvulsive therapy (ECT)?
 - a. Psychosis
 - b. Schizophrenia
 - c. Obsessive-compulsive disorder
 - d. Depression
 - e. Generalized anxiety disorder
3. Which of the following was the purpose of lobotomies?
 - a. To alleviate depression
 - b. To minimize delusions and hallucinations
 - c. To “erase” troubling memories
 - d. To recover repressed memories
 - e. To separate the reasoning centers of the brain from the emotional centers

Practice FRQs

1. Identify the category of drugs used to treat schizophrenia and the category of drugs used to treat obsessive-compulsive disorder. Then explain what each of these two categories of drugs does inside the brain.
2. Briefly describe four therapeutic lifestyle changes advocated by Stephen Ilardi, and describe their benefits. **(4 points)**

Answer

2 points: Antipsychotic medications are the preferred drug treatment for schizophrenia. They work by blocking dopamine receptors.

2 points: Antidepressant medications are the preferred drug treatment for obsessive-compulsive disorder. They work by blocking the reuptake of serotonin.

AP[®] Exam Practice Questions

Multiple-Choice Questions

- In an effort to help a child overcome a fear of dogs, a therapist pairs a trigger stimulus (something associated with dogs) with a new stimulus that causes a response that is incompatible with fear (for example, an appealing snack or toy). Which clinical orientation is this therapist using?
 - Psychodynamic
 - Behavioral
 - Biomedical
 - Client-centered
 - Humanistic
- Which of the following is a similarity between humanistic and psychoanalytic therapies?
 - Both approaches focus on the present more than the past.
 - Both approaches are more concerned with conscious than unconscious feelings.
 - Both approaches focus on taking immediate responsibility for one's feelings.
 - Both approaches focus on growth instead of curing illness.
 - Both approaches are generally considered insight therapies.

3. A psychotherapist who uses a blend of therapies is practicing what kind of approach?
 - a. Eclectic
 - b. Psychodynamic
 - c. Cognitive
 - d. Cognitive-behavioral
 - e. Humanistic
4. Some patients whose depression resists drugs have benefited from which experimental treatment?
 - a. Transference
 - b. Meta-analysis
 - c. Antipsychotic drugs
 - d. Deep-brain stimulation
 - e. Resistance
5. Which kind of drug is most closely associated with increasing the availability of norepinephrine or serotonin?
 - a. Antidepressant
 - b. Antipsychotic
 - c. Antianxiety
 - d. Mood-stabilizing
 - e. Muscle relaxant
6. Which of the following is seen as an effective treatment for severe depression that does not respond to drug therapy?
 - a. Lobotomy
 - b. Token economy
 - c. ECT
 - d. Crisis debriefing
 - e. EMDR therapy
7. Echoing, restating, and seeking clarification of what a person expresses (verbally or nonverbally) in a therapy session is called
 - a. active listening.
 - b. virtual reality exposure therapy.
 - c. systematic desensitization.
 - d. family therapy.
 - e. classical conditioning.
8. In the context of psychoanalytic theory, experiencing strong positive or negative feelings for your analyst is a sign of what?
 - a. Counterconditioning
 - b. Meta-analysis
 - c. Transference
 - d. Tardive dyskinesia
 - e. Aversive conditioning
9. In which kind of therapy would the therapist be most likely to note the following during a session: "Blocks in the flow of free associations indicate resistance"?
 - a. Cognitive therapy
 - b. Psychoanalysis
 - c. Client-centered therapy
 - d. Behavioral therapy
 - e. Person-centered therapy
10. Which kind of therapy below is most closely associated with the goal of altering thoughts and actions?
 - a. Aversive conditioning
 - b. Psychodynamic
 - c. Client-centered
 - d. Family
 - e. Cognitive-behavioral
11. Allowing people to discover, in a social context, that others have problems similar to their own is a unique benefit of what kind of therapy?
 - a. Psychodynamic
 - b. Psychopharmacological
 - c. Group
 - d. Cognitive
 - e. Humanistic
12. Which of the following therapeutic approaches is scientifically supported?
 - a. Recovered-memory therapies
 - b. Rebirthing therapies
 - c. Cognitive therapy
 - d. Energy therapies
 - e. Crisis debriefing
13. Most antipsychotic drugs mimic a certain neurotransmitter by blocking its activity at the receptor sites. These drugs affect which one of the following neurotransmitters?
 - a. Adrenaline
 - b. Epinephrine
 - c. Serotonin
 - d. Dopamine
 - e. Acetylcholine
14. Which of the following is *not* recommended by therapists as a way to help prevent or get over depression?
 - a. Recovered-memory therapies
 - b. Aerobic exercise
 - c. Light exposure
 - d. Increased social connections
 - e. Antirumination strategies

- 15.** A psychotherapist states, “Getting people to change what they say to themselves is an effective way to change their thinking.” This statement best exemplifies which kind of therapeutic approach?
- Behavioral
 - Psychodynamic
 - Biomedical
 - Cognitive
 - Active listening

Free-Response Questions

- 1.** Your friend Lawrence recently confided in you that he has been diagnosed with major depression. He heard about several different kinds of treatments: psychodynamic therapy, exposure therapy, REBT, SSRIs, and rTMS. Explain what you would tell Lawrence about how each type of therapy works and whether research indicates that it might be an effective treatment for major depression.

Rubric for Free-Response Question 1

1 point: Psychodynamic therapy involves a therapist and client attempting to gain perspective and insight into a client’s unconscious conflicts and anxieties. Outcome research indicates that psychodynamic therapy has had success with depression symptoms. 🔄 Pages 710–711

1 point: Exposure therapy exposes people to the things that they fear and avoid in order to reduce the fear or anxiety. This type of therapy is specifically focused on reducing specific anxiety symptoms and is not designed to treat depression. 🔄 Pages 717–718

1 point: Albert Ellis’ rational-emotive behavior therapy (REBT), a type of cognitive therapy, attempts to stop irrational thinking by challenging a person’s illogical, self-defeating assumptions. Since many of the symptoms of major depression involve negative, pessimistic thinking, this treatment is worth exploring as a treatment for depression. 🔄 Page 721

1 point: SSRIs, such as Zoloft, Paxil, and Prozac, work by partially blocking the reabsorption and removal of serotonin from synapses. The fact that more serotonin remains in the synapses serves to reduce the symptoms of depression. 🔄 Pages 741–743

1 point: Repetitive transcranial magnetic stimulation (rTMS) sends repeated pulses of magnetic energy into the brain, usually into the left frontal lobe. This approach has proven effective in the treatment of depression. 🔄 Page 745

- 2.** For each of the following pairs, first define the particular type of treatment referenced, then explain the rationale for using this therapy to treat an individual with the particular disorder with which it is paired.

- Bipolar disorder and the biomedical approach
- Phobias and systematic desensitization
- Dissociative identity disorder and psychoanalysis
- Addiction and group therapy

77 Prejudice and Discrimination

78 Aggression

79 Attraction

80 Altruism, Conflict, and Peacemaking

Dirk Willems faced a moment of decision in 1569. Threatened with torture and death as a member of a persecuted religious minority, he escaped from his Asperen, Holland, prison and fled across an ice-covered pond. His stronger and heavier jailer pursued him but fell through the ice and, unable to climb out, pled for help.

With his freedom in front of him, Willems acted with ultimate selflessness. He turned back and rescued his pursuer, who, under orders, took him back to captivity. A few weeks later Willems was condemned to be “executed with fire, until death ensues.” For his martyrdom, present-day Asperen has named a street in honor of its folk hero (Toews, 2004).

What drives people to feel contempt for religious minorities such as Dirk Willems, and to act so spitefully? And what motivated the selflessness of Willems’ response, and of so many who have died trying to save others? Indeed, what motivates any of us when we volunteer kindness and generosity toward others?

As such examples demonstrate, we are social animals. We may assume the best or the worst in others. We may approach them with closed fists or open arms. But as the novelist Herman Melville remarked, “We cannot live for ourselves alone. Our lives are connected by a thousand invisible threads.” *Social psychologists* explore these connections by scientifically studying how we *think about, influence, and relate* to one another.

Module 74

Attribution, Attitudes, and Actions

Module Learning Objectives

- 74-1** Identify what social psychologists study, and discuss how we tend to explain others' behavior and our own.
- 74-2** Explain whether what we think affects what we do, and whether what we do affects what we think.

Frances Roberts/Alamy

74-1 What do social psychologists study? How do we tend to explain others' behavior and our own?

Personality psychologists (Unit X) focus on the person. They study the personal traits and dynamics that explain why *different people* may act differently *in a given situation*, such as the one Willems faced. (Would you have helped the jailer out of the icy water?) **Social psychologists** focus on the situation. They study the social influences that explain why *the same person* will act differently in *different situations*. Might the jailer have acted differently—opting not to march Willems back to jail—under differing circumstances?

social psychology the scientific study of how we think about, influence, and relate to one another.

attribution theory the theory that we explain someone's behavior by crediting either the situation or the person's disposition.

fundamental attribution error the tendency for observers, when analyzing others' behavior, to underestimate the impact of the situation and to overestimate the impact of personal disposition.

The Fundamental Attribution Error

Our social behavior arises from our social cognition. Especially when the unexpected occurs, we want to understand and explain why people act as they do. After studying how people explain others' behavior, Fritz Heider (1958) proposed an **attribution theory**: We can attribute the behavior to the person's stable, enduring traits (a *dispositional attribution*). Or we can attribute it to the situation (a *situational attribution*).

For example, in class, we notice that Juliette seldom talks. At the game, Jack talks nonstop. That must be the sort of people they are, we decide. Juliette must be shy and Jack outgoing. Such attributions—to their dispositions—can be valid, because people do have enduring personality traits. But sometimes we fall prey to the **fundamental attribution error** (Ross, 1977): We overestimate the influence of personality and underestimate the influence of situations. In class, Jack may be as quiet as Juliette. Catch Juliette as the lead in the high school musical and you may hardly recognize your quiet classmate.

David Napolitan and George Goethals (1979) demonstrated the fundamental attribution error in an experiment with Williams College students. They had students talk, one at a time, with a young woman who acted either cold and critical or warm and friendly. Before the talks, the researchers told half the students that the woman's behavior would be spontaneous. They told the other half the truth—that they had instructed her to *act* friendly (or unfriendly).

Did hearing the truth affect students' impressions of the woman? Not at all! If the woman acted friendly, both groups decided she really was a warm person. If

SelectStock/Getty Images

she acted unfriendly, both decided she really was a cold person. They attributed her behavior to her personal disposition *even when told that her behavior was situational*—that she was merely acting that way for the purposes of the experiment.

The fundamental attribution error appears more often in some cultures than in others. Individualist Westerners more often attribute behavior to people's personal traits. People in East Asian cultures are somewhat more sensitive to the power of the situation (Heine & Ruby, 2010; Kitayama et al., 2009). This difference has appeared in experiments that asked people to view scenes, such as a big fish swimming. Americans focused more on the individual fish, and Japanese people more on the whole scene (Chua et al., 2005; Nisbett, 2003).

We all commit the fundamental attribution error. Consider: Is your AP® psychology teacher shy or outgoing? If you answer “outgoing,” remember that you know your teacher from one situation—the classroom, which demands outgoing behavior. Your teacher (who observes his or her own behavior not only in the classroom, but also with family, in meetings, when traveling) might say, “Me, outgoing? It all depends on the situation. In class or with good friends, yes, I’m outgoing. But at professional meetings, I’m really rather shy.” Outside their assigned roles, teachers seem less teacherly, presidents less presidential, lawyers less legalistic.

When we explain *our own* behavior, we are sensitive to how our behavior changes with the situation (Idson & Mischel, 2001). After behaving badly, for example, we recognize how the situation affected our actions (recall the *self-serving bias* discussed in Module 59). What about our own intentional and admirable actions? Those we attribute not to situations but to our own good reasons (Malle, 2006; Malle et al., 2007). We also are sensitive to the power of the situation when we explain the behavior of people we know well and have seen in different contexts. We are most likely to commit the fundamental attribution error when a stranger acts badly. Having only seen that red-faced fan screaming at the referee in the heat of competition, we may assume he is a bad person. But outside the stadium, he may be a good neighbor and a great parent.

Researchers have reversed the perspectives of actor and observer. They filmed two people interacting, with a camera behind each person. Then they showed each person a replay—filmed from the other person's perspective. This reversed their attributions of the behaviors (Lassiter & Irvine, 1986; Storms, 1973). Seeing things from the actor's perspective, the observers better appreciated the situation. (As we act, our eyes look outward; we see others' faces, not our own.) Taking the observer's point of view, the actors became more aware of their own personal style.

Reflecting on our past selves of 5 or 10 years ago also switches our perspective. Our present self adopts the observer's perspective and attributes our past behavior mostly to our traits (Pronin & Ross, 2006). In another 5 or 10 years, your today's self may seem like another person.

The way we explain others' actions, attributing them to the person or the situation, can have important real-life effects (Fincham & Bradbury, 1993; Fletcher et al., 1990). A person must decide whether to interpret another's friendliness as genuine, or motivated by self-interest (she just needs a ride). A jury must decide whether a shooting was malicious or in self-defense. A voter must decide whether a candidate's promises will be kept or forgotten. A partner must decide whether a loved one's tart-tongued remark reflects a bad day or a mean disposition.

Finally, consider the social and economic effects of attribution. How do we explain poverty or unemployment? In Britain, India, Australia, and the United States political conservatives tend to place the blame on the personal dispositions of the poor and unemployed: “People generally get what they deserve. Those who don't work are freeloaders. Those who take initiative can still get ahead” (Furnham, 1982; Pandey et al., 1982; Wagstaff, 1982; Zucker & Weiner, 1993). Political liberals (and social scientists) are more likely to blame past and present situations: “If you or I

AP® Exam Tip

Many students have not heard of the fundamental attribution error before taking a course in psychology. This concept often shows up on the AP® exam, so be sure you understand this well.

FYI

Some 7 in 10 college women report having experienced a man misattributing her friendliness as a sexual come-on (Jacques-Tiura et al., 2007).

“Otis, shout at that man to pull himself together.”

An attribution question Whether we attribute poverty and homelessness to social circumstances or to personal dispositions affects and reflects our political views.

Lee Snider/The Image Works

had to live with the same poor education, lack of opportunity, and discrimination, would we be any better off?" To understand and prevent terrorism, they say, consider the situations that breed terrorists. Better to drain the swamps than swat the mosquitoes.

The point to remember: Our attributions—to a person's disposition or to the situation—have real consequences.

Attitudes and Actions

74-2

Does what we think affect what we do, or does what we do affect what we think?

Attitudes are feelings, often influenced by our beliefs, that predispose our reactions to objects, people, and events. If we *believe* someone is threatening us, we may *feel* fear and anger toward the person and *act* defensively. The traffic between our attitudes and our actions is two-way. Our attitudes affect our actions. And our actions affect our attitudes.

Attitudes Affect Actions

Consider the climate-change debate. On one side are climate-change activists: "Almost all climate scientists are of one mind about the threat of global warming," reports *Science* magazine (Kerr, 2009). "It's real, it's dangerous, and the world needs to take action immediately." On the other side are climate-change deniers: The number of Americans who told Gallup pollsters that global warming is "generally exaggerated" increased from 30 percent in 2006 to 48 percent in 2010, and then dropped to 42 percent in 2012 (Saad, 2013).

Knowing that public attitudes affect public policies, activists on both sides are aiming to persuade. Persuasion efforts generally take two forms:

- **Peripheral route persuasion** doesn't engage systematic thinking, but does produce fast results as people respond to incidental cues (such as endorsements by respected people) and make snap judgments. A perfume ad may lure us with images of beautiful or famous people in love.
- **Central route persuasion** offers evidence and arguments that aim to trigger favorable thoughts. It occurs mostly when people are naturally analytical or involved in the issue. Environmental advocates may show us evidence of rising temperatures, melting glaciers, rising seas, and northward shifts in vegetation and animal life. Because it is more thoughtful and less superficial, it is more durable and more likely to influence behavior.

Those who attempt to persuade us are trying to influence our behavior by changing our attitudes. But other factors, including the situation, also influence behavior. Strong social pressures, for example, can weaken the attitude-behavior connection (Wallace et al., 2005).

attitude feelings, often influenced by our beliefs, that predispose us to respond in a particular way to objects, people, and events.

peripheral route persuasion occurs when people are influenced by incidental cues, such as a speaker's attractiveness.

central route persuasion occurs when interested people focus on the arguments and respond with favorable thoughts.

In roll-call votes, politicians will sometimes vote what their supporters demand, despite privately disagreeing with those demands (Nagourney, 2002). In such cases, external pressure overrides the attitude-behavior link.

Attitudes are especially likely to affect behavior when external influences are minimal, and when the attitude is stable, specific to the behavior, and easily recalled (Glasman & Albarraçín, 2006). One experiment used vivid, easily recalled information to persuade people that sustained tanning put them at risk for future skin cancer. One month later, 72 percent of the participants, and only 16 percent of those in a waitlist control group, had lighter skin (McClendon & Prentice-Dunn, 2001). Persuasion changed attitudes, which changed behavior.

Actions Affect Attitudes

Now consider a more surprising principle: Not only will people stand up for what they believe, they also will believe more strongly in what they have stood up for. Many streams of evidence confirm that *attitudes follow behavior* (**FIGURE 74.1**).

Figure 74.1

Attitudes follow behavior

Cooperative actions, such as those performed by people on sports teams, feed mutual liking. Such attitudes, in turn, promote positive behavior.

THE FOOT-IN-THE-DOOR PHENOMENON

How would you react if someone induced you to act against your beliefs? In many cases, people adjust their attitudes. During the Korean war, many U.S. prisoners of war were held in war camps run by Chinese communists. Without using brutality, the captors secured the prisoners' collaboration in various activities. Some merely ran errands or accepted favors. Others made radio appeals and false confessions. Still others informed on other prisoners and divulged military information. When the war ended, 21 prisoners chose to stay with the communists. More returned home "brainwashed"—convinced that communism was a good thing for Asia.

How did the Chinese captors achieve these amazing results? A key ingredient was their effective use of the **foot-in-the-door phenomenon**: They knew that people who agreed to a small request would find it easier to comply later with a larger one. The Chinese began with harmless requests, such as copying a trivial statement, but gradually escalated their demands (Schein, 1956). The next statement to be copied might list flaws of capitalism. Then, to gain privileges, the prisoners participated in group discussions, wrote self-criticisms, or uttered public confessions. After doing so, they often adjusted their beliefs to be more consistent with their public acts. The point is simple: To get people to agree to something big, start small and build (Cialdini, 1993). A trivial act makes the next act easier. Succumb to a temptation, and you will find the next temptation harder to resist.

foot-in-the-door phenomenon

the tendency for people who have first agreed to a small request to comply later with a larger request.

In dozens of experiments, researchers have coaxed people into acting against their attitudes or violating their moral standards, with the same result: Doing becomes believing. After giving in to a request to harm an innocent victim—by making nasty comments or delivering electric shocks—people begin to disparage their victim. After speaking or writing on behalf of a position they have qualms about, they begin to believe their own words.

Fortunately, the attitudes-follow-behavior principle works with good deeds as well. The foot-in-the-door tactic has helped boost charitable contributions, blood donations, and product sales. In one classic experiment, researchers posing as safe-driving volunteers asked Californians to permit the installation of a large, poorly lettered “Drive Carefully” sign in their front yards. Only 17 percent consented. They approached other home owners with a small request first: Would they display a 3-inch-high “Be a Safe Driver” sign? Nearly all readily agreed. When reapproached two weeks later to allow the large, ugly sign in their front yards, 76 percent consented (Freedman & Fraser, 1966). To secure a big commitment, it often pays to put your foot in the door: Start small and build.

Racial attitudes likewise follow behavior. In the years immediately following the introduction of school desegregation in the United States and the passage of the Civil Rights Act of 1964, White Americans expressed diminishing racial prejudice. And as Americans in different regions came to act more alike—thanks to more uniform national standards against discrimination—they began to think more alike. Experiments confirm the observation: Moral action strengthens moral convictions.

ROLE PLAYING AFFECTS ATTITUDES

When you adopt a new **role**—when you leave middle school and start high school, become a college student, or begin a new job—you strive to follow the social prescriptions. At first, your behaviors may feel phony, because you are *acting* a role. Soldiers may at first feel they are playing war games. Newlyweds may feel they are “playing house.” Before long, however, what began as playacting in the theater of life becomes you. Researchers have confirmed this effect by assessing people’s attitudes before and after they adopt a new role, sometimes in laboratory situations, sometimes in everyday situations, such as before and after taking a job.

Role playing morphed into real life in one famous study in which male college students volunteered to spend time in a simulated prison. Stanford psychologist Philip Zimbardo (1972) randomly assigned some volunteers to be guards. He gave them uniforms, clubs, and whistles and instructed them to enforce certain rules. Others became prisoners, locked in barren cells and forced to wear humiliating outfits. For a day or two, the volunteers self-consciously “played” their roles. Then the simulation became real—too real. Most guards developed disparaging attitudes, and some devised cruel and degrading routines. One by one, the prisoners broke down, rebelled, or became passively resigned. After only six days, Zimbardo called off the study.

“Fake it until you make it.”
—ALCOHOLICS ANONYMOUS SAYING

role a set of expectations (norms) about a social position, defining how those in the position ought to behave.

The power of the situation In his 1972 Stanford Prison simulation, Philip Zimbardo created a toxic situation (left). Those assigned to the guard role soon degraded the prisoners. In real life in 2004, some U.S. military guards tormented Iraqi prisoners at the U.S.-run Abu Ghraib prison (right). To Zimbardo (2004, 2007), it was a bad barrel rather than a few bad apples that led to the Abu Ghraib atrocities: “When ordinary people are put in a novel, evil place, such as most prisons, Situations Win, People Lose.”

Philip G. Zimbardo, Inc.

AP Photo

Role playing can train torturers (Staub, 1989). In the early 1970s, the Greek military government eased men into their roles. First, a trainee stood guard outside an interrogation cell. After this “foot in the door” step, he stood guard inside. Only then was he ready to become actively involved in the questioning and torture. What we do, we gradually become.

Yet people differ. In Zimbardo’s Stanford Prison simulation and in other atrocity-producing situations, some people have succumbed to the situation and others have not (Carnahan & McFarland, 2007; Haslam & Reicher, 2007; Mastroianni & Reed, 2006; Zimbardo, 2007). Person and situation interact. Much as water dissolves salt but not sand, so toxic situations corrupt some people but not others (Johnson, 2007).

COGNITIVE DISSONANCE: RELIEF FROM TENSION

So far we have seen that actions can affect attitudes, sometimes turning prisoners into collaborators, doubters into believers, and compliant guards into abusers. But why? One explanation is that when we become aware that our attitudes and actions don’t coincide, we experience tension, or *cognitive dissonance*. To relieve such tension, according to Leon Festinger’s (1957) **cognitive dissonance theory**, we often bring our attitudes into line with our actions.

Dozens of experiments have explored this cognitive dissonance phenomenon. Many have made people feel responsible for behavior that clashed with their attitudes and had foreseeable consequences. In one of these experiments, you might agree for a measly \$2 to help a researcher by writing an essay that supports something you don’t believe in (perhaps a school vending machine tax). Feeling responsible for the statements (which are inconsistent with your attitudes), you would probably feel dissonance, especially if you thought an administrator would be reading your essay. To reduce the uncomfortable tension you might start believing your phony words. At such times, it’s as if we rationalize, “If I chose to do it (or say it), I must believe in it.” The less coerced and more responsible we feel for a troubling act, the more dissonance we feel. The more dissonance we feel, the more motivated we are to find consistency, such as changing our attitudes to help justify the act.

The pressure to reduce dissonance helps explain the evolution of American attitudes toward the U.S. invasion of Iraq. When the war began, the stated reason for the invasion was the presumed threat of Saddam Hussein’s weapons of mass destruction (WMD). Would the war be justified if Iraq did not have WMD? Only 38 percent of Americans surveyed said it would be (Gallup, 2003). Nearly 80 percent believed such weapons would be found (Duffy, 2003; Newport et al., 2003). When no WMD were found, many Americans felt dissonance, which was heightened by their awareness of the war’s financial and human costs, by scenes of chaos in Iraq, and by inflamed anti-American and pro-terrorist sentiments in some parts of the world.

To reduce dissonance, some people revised their memories of the war’s rationale. The invasion then became a movement to liberate an oppressed people and promote democracy in the Middle East. Before long, 58 percent of Americans—a majority—said they supported the war even if no WMD were found (Gallup, 2003).

The attitudes-follow-behavior principle has a heartening implication: We cannot directly control all our feelings, but we can influence them by altering our behavior. (Recall from Module 42 the emotional effects of facial expressions and of body postures.) If we are down in the dumps, we can do as cognitive-behavioral therapists advise and talk in more positive, self-accepting ways with fewer self-put-downs. If we are unloving, we can become more loving by behaving as if we were so—by doing thoughtful things, expressing affection, giving affirmation. That helps explain why teens’ doing volunteer work promotes a compassionate identity. “Assume a virtue, if you have it not,” says Hamlet to his mother. “For use can almost change the stamp of nature.” Pretense can become reality. Conduct sculpts character. What we do we become.

The point to remember: Cruel acts shape the self. But so do acts of good will. Act as though you like someone, and you soon may. Changing our behavior can change how we think about others and how we feel about ourselves.

Regarding U.S. President Lyndon Johnson’s commitment to the Vietnam war: “A president who justifies his actions only to the public might be induced to change them. A president who has justified his actions to himself, believing that he has the truth, becomes impervious to self-correction.” -CAROL TAVRIS AND ELLIOT ARONSON, *MISTAKES WERE MADE (BUT NOT BY ME)*, 2007

cognitive dissonance theory

the theory that we act to reduce the discomfort (dissonance) we feel when two of our thoughts (cognitions) are inconsistent. For example, when we become aware that our attitudes and our actions clash, we can reduce the resulting dissonance by changing our attitudes.

“Sit all day in a moping posture, sigh, and reply to everything with a dismal voice, and your melancholy lingers. . . . If we wish to conquer undesirable emotional tendencies in ourselves, we must . . . go through the outward movements of those contrary dispositions which we prefer to cultivate.” -WILLIAM JAMES, *PRINCIPLES OF PSYCHOLOGY*, 1890

Before You Move On

▶ ASK YOURSELF

Do you have an attitude or tendency you would like to change? Using the attitudes-follow-behavior principle, how might you go about changing that attitude?

▶ TEST YOURSELF

Driving to school one snowy day, Marco narrowly misses a car that slides through a red light. “Slow down! What a terrible driver,” he thinks to himself. Moments later, Marco himself slips through an intersection and yelps, “Wow! These roads are awful. The city plows need to get out here.” What social psychology principle has Marco just demonstrated? Explain.

Answers to the Test Yourself questions can be found in Appendix E at the end of the book.

Module 74 Review

74-1

What do social psychologists study? How do we tend to explain others' behavior and our own?

- *Social psychologists* focus on how we think about, influence, and relate to one another. They study the social influences that explain why the same person will act differently in different situations.
- When explaining others' behavior, we may commit the *fundamental attribution error* (underestimating the influence of the situation and overestimating the effects of personality). When explaining our own behavior, we more readily attribute it to the influence of the situation.

74-2

Does what we think affect what we do, or does what we do affect what we think?

- *Attitudes* are feelings, often influenced by our beliefs, that predispose us to respond in certain ways.
- *Peripheral route persuasion* uses incidental cues (such as celebrity endorsement) to try to produce fast but relatively thoughtless changes in attitudes.
- *Central route persuasion* offers evidence and arguments to trigger thoughtful responses.
- When other influences are minimal, attitudes that are stable, specific, and easily recalled can affect our actions.
- Actions can modify attitudes, as in the *foot-in-the-door phenomenon* (complying with a large request after having agreed to a small request) and role playing (acting a social part by following guidelines for expected behavior).
- When our attitudes don't fit with our actions, *cognitive dissonance theory* suggests that we will reduce tension by changing our attitudes to match our actions.

Multiple-Choice Questions

1. What do we call the tendency for observers to underestimate the impact of the situation and overestimate the impact of personal disposition?
 - a. Peripheral route persuasion
 - b. Social psychology
 - c. Attribution theory
 - d. Fundamental attribution error
 - e. Central route persuasion
2. Which of the following best describes a feeling, often influenced by a belief, that predisposes one to respond in a particular way to people and events?
 - a. Central route persuasion
 - b. Anger
 - c. Emotion
 - d. Foot-in-the-door phenomenon
 - e. Attitude
3. Which of the following best explains why we act to reduce the discomfort we feel when two of our thoughts are inconsistent?
 - a. Cognitive dissonance theory
 - b. Power of the situation
 - c. Foot-in-the-door phenomenon
 - d. Role theory
 - e. Fundamental attribution error

Practice FRQs

1. Explain the fundamental attribution error.

Answer

1 point: The fundamental attribution error occurs when we are analyzing someone's behavior.

2 points: In order for the fundamental attribution error to occur, the person analyzing must underestimate the role of the situation and overestimate the disposition of the person whose behavior is being analyzed.

2. Explain the difference between peripheral route persuasion and central route persuasion.

(4 points)

Module 75

Conformity and Obedience

Module Learning Objectives

- 75-1** Describe automatic mimicry, and explain how conformity experiments reveal the power of social influence.
- 75-2** Describe what we learned about the power of social influence from Milgram's obedience experiments.

"Have you ever noticed how one example—good or bad—can prompt others to follow? How one illegally parked car can give permission for others to do likewise? How one racial joke can fuel another?" -MARIAN WRIGHT EDELMAN, *THE MEASURE OF OUR SUCCESS*, 1992

Social psychology's great lesson is the enormous power of social influence. This influence can be seen in our conformity, our obedience to authority, and our group behavior. Suicides, bomb threats, airplane hijackings, and UFO sightings all have a curious tendency to come in clusters. On most high school campuses, jeans are the dress code; on New York's Wall Street or London's Bond Street, dress suits are the norm. When we know how to act, how to groom, how to talk, life functions smoothly. Armed with social influence principles, advertisers, fundraisers, and campaign workers aim to sway our decisions to buy, to donate, to vote. Isolated with others who share their grievances, dissenters may gradually become rebels, and rebels may become terrorists. Let's examine the pull of these social strings. How strong are they? How do they operate? When do we break them?

Conformity: Complying With Social Pressures

- 75-1** What is automatic mimicry, and how do conformity experiments reveal the power of social influence?

Conforming to nonconformity

Are these students asserting their individuality or identifying themselves with others of the same microculture?

Automatic Mimicry

Fish swim in schools. Birds fly in flocks. And humans, too, tend to go with their group, to think what it thinks and do what it does. Behavior is contagious. Chimpanzees are more likely to yawn after observing another chimpanzee yawn (Anderson et al., 2004). Ditto for humans. If one of us yawns, laughs, coughs, stares at the sky, or checks a cell phone, others in our group will soon do the same. Like the chameleon lizards that take on the color of their surroundings, we humans take on the emotional tones of those around us. Just hearing someone reading a neutral text in either a happy- or sad-sounding voice creates "mood contagion" in listeners (Neumann & Strack, 2000). We are natural mimics, unconsciously imitating others' expressions, postures, and voice tones.

Tanya Chartrand and John Bargh captured this mimicry, which they call the *chameleon effect* (Chartrand & Bargh, 1999). They had students work in a room alongside another person, who was actually a confederate working for the experimenters. Sometimes the confederates rubbed their own face. Sometimes they shook their foot. Sure enough, the students tended to rub their face when with the face-rubbing person and shake their foot when with the foot-shaking person. Other studies have found people synchronizing their grammar to match material they are reading or people they are hearing (Ireland & Pennebaker, 2010). Perhaps we should not be surprised then that intricate studies show that obesity, sleep loss, drug use, loneliness, and happiness spread through social networks (Christakis & Fowler, 2009). We and our friends form a social system.

Automatic mimicry helps us to *empathize*—to feel what others are feeling. This helps explain why we feel happier around happy people than around depressed people. It also helps explain why studies of groups of British nurses and accountants have revealed *mood linkage*—sharing up and down moods (Totterdell et al., 1998). Empathic people yawn more after seeing others yawn (Morrison, 2007). And empathic mimicking fosters fondness (van Baaren et al., 2003, 2004). Perhaps you’ve noticed that when someone nods their head as you do and echoes your words, you feel a certain rapport and liking?

Suggestibility and mimicry sometimes lead to tragedy. In the eight days following the 1999 shooting rampage at Colorado’s Columbine High School, every U.S. state except Vermont experienced threats of copycat violence. Pennsylvania alone recorded 60 such threats (Cooper, 1999). Sociologist David Phillips and his colleagues (1985, 1989) found that suicides, too, sometimes increase following a highly publicized suicide. In the wake of screen idol Marilyn Monroe’s suicide on August 5, 1962, for example, the number of suicides in the United States exceeded the usual August count by 200.

What causes behavior clusters? Do people act similarly because of their influence on one another? Or because they are simultaneously exposed to the same events and conditions? Seeking answers to such questions, social psychologists have conducted experiments on group pressure and conformity.

“When I see synchrony and mimicry—whether it concerns yawning, laughing, dancing, or aping—I see social connection and bonding.” -PRIMATOLOGIST FRANS DE WAAL “THE EMPATHY INSTINCT,” 2009

NON SEQUITUR

by WILEY

Conformity and Social Norms

Suggestibility and mimicry are subtle types of **conformity**—adjusting our behavior or thinking toward some group standard. To study conformity, Solomon Asch (1955) devised a simple test. As a participant in what you believe is a study of visual perception, you arrive in time to take a seat at a table with five other people. The experimenter asks the group to state, one by one, which of three comparison lines is identical to a standard line. You see clearly that the answer is Line 2, and you await your turn to say so. Your boredom begins to show when the next set of lines proves equally easy.

Now comes the third trial, and the correct answer seems just as clear-cut (**FIGURE 75.1** on the next page). But the first person gives what strikes you as a wrong answer: “Line 3.” When the second person and then the third and fourth give the same wrong

conformity adjusting our behavior or thinking to coincide with a group standard.

Figure 75.1

Asch's conformity experiments

Which of the three comparison lines is equal to the standard line? What do you suppose most people would say after hearing five others say, “Line 3”? In this photo from one of Asch’s experiments, the student in the center shows the severe discomfort that comes from disagreeing with the responses of other group members (in this case, accomplices of the experimenter).

answer, you sit up straight and squint. When the fifth person agrees with the first four, you feel your heart begin to pound. The experimenter then looks to you for your answer. Torn between the unanimity voiced by the five others and the evidence of your own eyes, you feel tense and suddenly unsure. You hesitate before answering, wondering whether you should suffer the discomfort of being the oddball. What answer do you give?

In Asch’s experiments, college students, answering questions alone, erred less than 1 percent of the time. But what about when several others—confederates working for the experimenter—answered incorrectly? Although most people told the truth even when others did not, Asch was disturbed by his result: More than one-third of the time, these “intelligent and well-meaning” college students were then “willing to call white black” by going along with the group.

Later investigations have not always found as much conformity as Asch found, but they have revealed that we are more likely to conform when we

- are made to feel incompetent or insecure.
- are in a group with at least three people.
- are in a group in which everyone else agrees. (If just one other person disagrees, the odds of our disagreeing greatly increase.)
- admire the group’s status and attractiveness.
- have not made a prior commitment to any response.
- know that others in the group will observe our behavior.
- are from a culture that strongly encourages respect for social standards.

Why do we so often think what others think and do what they do? Why in college residence halls do students’ attitudes become more similar to those living near them (Cullum & Harton, 2007)? Why in college classrooms are hand-raised answers to controversial questions less diverse than anonymous electronic clicker responses (Stowell et al., 2010)? Why do we clap when others clap, eat as others eat, believe what others believe, say what others say, even see what others see?

Frequently, we conform to avoid rejection or to gain social approval. In such cases, we are responding to **normative social influence**. We are sensitive to *social norms*—understood rules for accepted and expected behavior—because the price we pay for being different can be severe. We need to belong. To get along, we go along.

At other times, we conform because we want to be accurate. Groups provide information, and only an uncommonly stubborn person will never listen to others. “Those who never retract their opinions love themselves more than they love truth,” observed Joseph Joubert, an eighteenth-century French essayist. When we accept others’ opinions about reality, we are responding to **informational social influence**. As Rebecca Denton demonstrated in 2004, sometimes it pays to assume others are right and to follow their lead. Denton set a record for the furthest distance driven on the wrong side of a British divided highway—30 miles, with only one minor sideswipe, before the motorway ran out and police were able

normative social influence

influence resulting from a person’s desire to gain approval or avoid disapproval.

informational social influence

influence resulting from one’s willingness to accept others’ opinions about reality.

to puncture her tires. Denton, who was intoxicated, later explained that she thought the hundreds of other drivers coming at her were all on the wrong side of the road (Woolcock, 2004).

Is conformity good or bad? The answer depends partly on our culturally influenced values. Western Europeans and people in most English-speaking countries tend to prize individualism. People in many Asian, African, and Latin American countries place a higher value on honoring group standards. In social influence experiments across 17 countries, conformity rates have been lower in individualist cultures (Bond & Smith, 1996). American university students, for example, tend to see themselves, in domains ranging from consumer purchases to political views, as less conforming than others (Pronin et al., 2007). We are, in our own eyes, individuals amid a crowd of sheep.

"I love the little ways you're identical to everyone else."

Obedience: Following Orders

75-2

What did Milgram's obedience experiments teach us about the power of social influence?

Social psychologist Stanley Milgram (1963, 1974), a student of Solomon Asch, knew that people often give in to social pressures. But how would they respond to outright commands? To find out, he undertook what became social psychology's most famous, controversial, and influential experiments (Benjamin & Simpson, 2009).

Imagine yourself as one of the nearly 1000 people who took part in Milgram's 20 experiments. You respond to an advertisement for participants in a Yale University psychology study of the effect of punishment on learning. Professor Milgram's assistant asks you and another person to draw slips from a hat to see who will be the "teacher" and who will be the "learner." You draw the "teacher" slip and are asked to sit down in front of a machine, which has a series of labeled switches. The learner, a mild and submissive-seeming man, is led to an adjoining room and strapped into a chair. From the chair, wires run through the wall to "your" machine. You are given your task: Teach and then test the learner on a list of word pairs. If the learner gives a wrong answer, you are to flip a switch to deliver a brief electric shock. For the first wrong answer, you will flip the switch labeled "15 Volts—Slight Shock." With each succeeding error, you will move to the next higher voltage. The researcher demonstrates by flipping the first switch. Lights flash, relay switches click on, and an electric buzzing fills the air.

The experiment begins, and you deliver the shocks after the first and second wrong answers. If you continue, you hear the learner grunt when you flick the third, fourth, and fifth switches. After you activate the eighth switch ("120 Volts—Moderate Shock"), the learner cries out that the shocks are painful. After the tenth switch ("150 Volts—Strong Shock"), he begins shouting. "Get me out of here! I won't be in the experiment anymore! I refuse to go on!" You draw back, but the stern experimenter prods you: "Please continue—the experiment requires that you continue." You resist, but the experimenter insists, "It is absolutely essential that you continue," or "You have no other choice, you *must* go on."

If you obey, you hear the learner shriek in apparent agony as you continue to raise the shock level after each new error. After the 330-volt level, the learner refuses to answer and falls silent. Still, the experimenter pushes you toward the final, 450-volt switch. Ask the question, he says, and if no correct answer is given, administer the next shock level.

Would you follow the experimenter's commands to shock someone? At what level would you refuse to obey? Milgram asked that question in a survey before he started his experiments. Most people were sure they would stop playing such a sadistic-seeming role soon after the learner first indicated pain, certainly before he shrieked in agony. Forty psychiatrists agreed with that prediction when Milgram asked them. Were the predictions accurate? Not even close. When Milgram conducted the experiment with men aged 20 to 50, he was astonished. More than 60 percent complied fully—right up to the last switch.

AP® Exam Tip

Three of the most famous research projects in psychology were done by social psychologists, and you've now read about them all. Milgram, Asch, and Zimbardo (from the last module) are all likely to appear on the AP® exam.

Stanley Milgram (1933–1984)

This social psychologist's obedience experiments "belong to the self-understanding of literate people in our age" (Sabini, 1986).

Stanley Milgram, from the film "Obedience." Rights held by Alexandra Milgram

Figure 75.2

Milgram's follow-up obedience experiment

In a repeat of the earlier experiment, 65 percent of the adult male "teachers" fully obeyed the experimenter's commands to continue. They did so despite the "learner's" earlier mention of a heart condition and despite hearing cries of protest after they administered what they thought were 150 volts and agonized protests after 330 volts. (Data from Milgram, 1974.)

Even when Milgram ran a new study, with 40 new teachers, and the learner complained of a "slight heart condition," the results were similar. A full 65 percent of the new teachers obeyed every one of the experimenter's commands, right up to 450 volts (**FIGURE 75.2**).

Cultures change over time. Are people today less likely to obey an order to hurt someone? To find out, Jerry Burger (2009) replicated Milgram's basic experiment. Seventy percent of the participants obeyed up to the 150-volt point, a slight reduction from Milgram's result. And in a French reality TV show replication, 80 percent of people, egged on by a cheering audience, obeyed and tortured a screaming victim (de Moraes, 2010).

Could Milgram's findings reflect some aspect of gender behavior found only in males? *No*. In 10 later studies, women obeyed at rates similar to men's (Blass, 1999).

Did the teachers figure out the hoax—that no real shock was being delivered and the learner was in fact a confederate who was pretending to feel pain? Did they realize the experiment was really testing their willingness to comply with commands to inflict punishment? *No*. The teachers typically displayed genuine distress: They perspired, trembled, laughed nervously, and bit their lips.

Milgram's use of deception and stress triggered a debate over his research ethics. In his own defense, Milgram pointed out that, after the participants learned of the deception and actual research purposes, virtually none regretted taking part (though perhaps by then the participants had reduced their dissonance). When 40 of the teachers who had agonized most were later interviewed by a psychiatrist, none appeared to be suffering emotional aftereffects. All in all, said Milgram, the experiments provoked less enduring stress than university students experience when facing and failing big exams (Blass, 1996).

In later experiments, Milgram discovered some things that do influence people's behavior. When he varied the situation, the percentage of participants who fully obeyed ranged from 0 to 93 percent. Obedience was highest when

- *the person giving the orders was close at hand and was perceived to be a legitimate authority figure.* (Such was the case in 2005 when Temple University's basketball coach sent a 250-pound bench player, Nehemiah Ingram, into a game with instructions to commit "hard fouls." Following orders, Ingram fouled out in four minutes after breaking an opposing player's right arm.)
- *the authority figure was supported by a prestigious institution.* (Compliance was somewhat lower when Milgram dissociated his experiments from Yale University.)

- *the victim was depersonalized or at a distance, even in another room.* (Similarly, many soldiers in combat either have not fired their rifles at an enemy they can see, or have not aimed them properly. Such refusals to kill were rare among soldiers who were operating long-distance artillery or aircraft weapons [Padgett, 1989].)
- *there were no role models for defiance.* (Teachers did not see any other participant disobey the experimenter.)

The power of legitimate, close-at-hand authorities was apparent among those who followed orders to carry out the Holocaust atrocities. Obedience alone does not explain the Holocaust. Anti-Semitic ideology produced eager killers as well (Mastroianni, 2002). But obedience was a factor. In the summer of 1942, nearly 500 middle-aged German reserve police officers were dispatched to German-occupied Jozefow, Poland. On July 13, the group's visibly upset commander informed his recruits, mostly family men, of their orders. They were to round up the village's Jews, who were said to be aiding the enemy. Able-bodied men would be sent to work camps, and all the rest would be shot on the spot.

The commander gave the recruits a chance to refuse to participate in the executions. Only about a dozen immediately refused. Within 17 hours, the remaining 485 officers killed 1500 helpless women, children, and elderly, shooting them in the back of the head as they lay face down. Hearing the victims' pleas, and seeing the gruesome results, some 20 percent of the officers did eventually dissent, managing either to miss their victims or to wander away and hide until the slaughter was over (Browning, 1992). In real life, as in Milgram's experiments, those who resisted did so early, and they were the minority.

Another story was being played out in the French village of Le Chambon. There, French Jews destined for deportation to Germany were sheltered by villagers who openly defied orders to cooperate with the "New Order." The villagers' Protestant ancestors had themselves been persecuted, and their pastors taught them to "resist whenever our adversaries will demand of us obedience contrary to the orders of the Gospel" (Rochat, 1993). Ordered by police to give a list of sheltered Jews, the head pastor modeled defiance: "I don't know of Jews, I only know of human beings." Without realizing how long and terrible the war would be, or how much punishment and poverty they would suffer, the resisters made an initial commitment to resist. Supported by their beliefs, their role models, their interactions with one another, and their own initial acts, they remained defiant to the war's end.

Lest we presume that obedience is always evil and resistance is always good, consider the obedience of British soldiers who, in 1852, were traveling with civilians aboard the steamship *Birkenhead*. As they neared their South African port, the *Birkenhead* became impaled on a rock. To calm the passengers and permit an orderly exit of civilians via the three available lifeboats, soldiers who were not assisting the passengers or working the pumps lined up at parade rest. "Steady, men!" said their officer as the lifeboats pulled away. Heroically, no one frantically rushed to claim a lifeboat seat. As the boat sank, all were plunged into the sea, most to be drowned or devoured by sharks. For almost a century, noted James Michener (1978), "the Birkenhead drill remained the measure by which heroic behavior at sea was measured."

AP/Wide World Photos, Inc.

Standing up for democracy

Some individuals—roughly one in three in Milgram's experiments—resist social coercion, as did this unarmed man in Beijing, by single-handedly challenging an advancing line of tanks the day after the 1989 Tiananmen Square student uprising was suppressed.

The Argory, County Armagh, Northern Ireland/The Bridgeman Art Library

The "Birkenhead drill" To calm and give priority to passengers, soldiers obeyed orders to line up on deck as their ship sank.

Lessons From the Obedience Studies

What do the Milgram experiments teach us about ourselves? How does flicking a shock switch relate to everyday social behavior? Recall from Module 6 that psychological experiments aim not to re-create the literal behaviors of everyday life but to capture and explore the underlying processes that shape those behaviors. Participants in the Milgram experiments confronted a dilemma we all face frequently: Do I adhere to my own standards, or do I respond to others?

In these experiments and their modern replications, participants were torn. Should they respond to the pleas of the victim or the orders of the experimenter? Their moral sense warned them not to harm another, yet it also prompted them to obey the experimenter and to be a good research participant. With kindness and obedience on a collision course, obedience usually won.

These experiments demonstrated that strong social influences can make people conform to falsehoods or capitulate to cruelty. Milgram saw this as the fundamental lesson of this work: “Ordinary people, simply doing their jobs, and without any particular hostility on their part, can become agents in a terrible destructive process” (1974, p. 6).

Focusing on the end point—450 volts, or someone’s real-life reprehensible deceit or violence—we can hardly comprehend the inhumanity. But we ignore how they get there, in tiny increments. Milgram did not entrap his teachers by asking them first to zap learners with enough electricity to make their hair stand on end. Rather, he exploited the foot-in-the-door effect, beginning with a little tickle of electricity and escalating step by step. In the minds of those throwing the switches, the small action became justified, making the next act tolerable. In Jozefow and Le Chambon, as in Milgram’s experiments, those who resisted usually did so early. After the first acts of compliance or resistance, attitudes began to follow and justify behavior.

So it happens when people succumb, gradually, to evil. In any society, great evils sometimes grow out of people’s compliance with lesser evils. The Nazi leaders suspected that most German civil servants would resist shooting or gassing Jews directly, but they found them surprisingly willing to handle the paperwork of the Holocaust (Silver & Geller, 1978). Milgram found a similar reaction in his experiments. When he asked 40 men to administer the learning test while someone else did the shocking, 93 percent complied. Cruelty does not require devilish villains. All it takes is ordinary people corrupted by an evil situation. Ordinary students may follow orders to haze initiates into their group. Ordinary employees may follow orders to produce and market harmful products. Ordinary soldiers may follow orders to punish and then torture prisoners (Lankford, 2009).

“I was only following orders.”
-ADOLF EICHMANN, DIRECTOR OF
NAZI DEPORTATION OF JEWS TO
CONCENTRATION CAMPS

“The normal reaction to an
abnormal situation is abnormal
behavior.” -JAMES WALLER,
*BECOMING EVIL: HOW ORDINARY
PEOPLE COMMIT GENOCIDE AND MASS
KILLING*, 2007

Before You Move On

▶ ASK YOURSELF

How have you found yourself conforming, or perhaps “conforming to nonconformity”? In what ways have you seen others identifying themselves with those of the same culture or microculture?

▶ TEST YOURSELF

What types of situations have researchers found to be most likely to encourage obedience in participants?

Answers to the Test Yourself questions can be found in Appendix E at the end of the book.

Module 75 Review

75-1 What is automatic mimicry, and how do conformity experiments reveal the power of social influence?

- Automatic mimicry (the chameleon effect), our tendency to unconsciously imitate others' expressions, postures, and voice tones, is a form of *conformity*.
- Solomon Asch and others have found that we are most likely to adjust our behavior or thinking to coincide with a group standard when (a) we feel incompetent or insecure, (b) our group has at least three people, (c) everyone else agrees, (d) we admire the group's status and attractiveness, (e) we have not already committed to another response, (f) we know we are being observed, and (g) our culture encourages respect for social standards.
- We may conform to gain approval (*normative social influence*) or because we are willing to accept others' opinions as new information (*informational social influence*).

75-2 What did Milgram's obedience experiments teach us about the power of social influence?

- Stanley Milgram's experiments—in which people obeyed orders even when they thought they were harming another person—demonstrated that strong social influences can make ordinary people conform to falsehoods or give in to cruelty.
- Obedience was highest when (a) the person giving orders was nearby and was perceived as a legitimate authority figure; (b) the research was supported by a prestigious institution; (c) the victim was depersonalized or at a distance; and (d) there were no role models for defiance.

Multiple-Choice Questions

- Which of the following is an example of conformity?
 - Malik has had a series of dogs over the years. Each has learned to curl up at his feet when he was watching television.
 - Renee begins to buy the same brand of sweatshirt that most of the kids in her school are wearing.
 - Jonah makes sure to arrive home before his curfew because he knows he will be grounded if he doesn't.
 - Yuri makes sure to arrive home before her curfew because she does not want her parents to be disappointed in her.
 - Terry cranks it up a notch during volleyball practice because the team captain has been on her case for not showing enough effort.
- Groundbreaking research on obedience was conducted by
 - Albert Bandura.
 - Solomon Asch.
 - Philip Zimbardo.
 - Stanley Milgram.
 - John Bargh.
- Classic studies of obedience indicate that about _____ of the participants were willing to administer what they believed to be 450-volt shocks to other humans.
 - one-tenth
 - one-half
 - one-third
 - one-fourth
 - two-thirds
- Obedience to authority when the authority figure is asking someone to shock another person is highest when
 - the person receiving orders has witnessed others defy the authority figure.
 - the person receiving orders wonders whether the person giving orders has legitimate authority.
 - the victim receiving the shocks is physically near the person receiving orders.
 - the authority figure is from a prestigious institution.
 - the person receiving the orders is female.

Practice FRQs

1. Define conformity and obedience. Then, provide an example of each.

Answer

1 point: Conformity is adjusting our behavior or thinking to coincide with a group standard.

1 point: Obedience is following the orders of an authority figure.

1 point: Any correct example of conformity. Answers will vary.

1 point: Any correct example of obedience. Answers will vary.

2. Stanley Milgram's research on obedience triggered a debate over ethics. Explain the concern and Milgram's defense.

(2 points)

Module 76

Group Behavior

Module Learning Objectives

- 76-1** Describe how our behavior is affected by the presence of others.
- 76-2** Explain group polarization and groupthink, and discuss the power of the individual.
- 76-3** Describe how behavior is influenced by cultural norms.

- 76-1** How is our behavior affected by the presence of others?

Imagine yourself standing in a room, holding a fishing pole. Your task is to wind the reel as fast as you can. On some occasions you wind in the presence of another participant who is also winding as fast as possible. Will the other's presence affect your own performance?

In one of social psychology's first experiments, Norman Triplett (1898) found that adolescents would wind a fishing reel faster in the presence of someone doing the same thing. He and later social psychologists studied how others' presence affects our behavior. Group influences operate in such simple groups—one person in the presence of another—and in more complex groups.

Social Facilitation

Triplett's finding—of strengthened performance in others' presence—is called **social facilitation**. But on tougher tasks (learning nonsense syllables or solving complex multiplication problems), people perform worse when observers or others working on the same task are present. Further studies revealed that the presence of others sometimes helps and sometimes hinders performance (Guerin, 1986; Zajonc, 1965). Why? Because when others observe us, we become aroused, and this arousal amplifies our other reactions. It strengthens our most *likely* response—the correct one on an easy task, an incorrect one on a difficult task. Thus, expert pool players who made 71 percent of their shots when alone made 80 percent when four people came to watch them (Michaels et al., 1982). Poor shooters, who made 36 percent of their shots when alone, made only 25 percent when watched.

The energizing effect of an enthusiastic audience probably contributes to the home advantage that has shown up in studies of more than a quarter-million college and professional athletic events in various countries (Jamieson, 2010). Home teams win about 6 in 10 games (somewhat fewer for baseball, cricket, and football, somewhat more for basketball, rugby, and soccer—see **TABLE 76.1** on the next page).

AP® Exam Tip

As you work through this material, identify examples of group behavior in your own life. Then, compare your examples with a classmate's. This is a great way to make psychology come alive and to study effectively.

social facilitation improved performance on simple or well-learned tasks in the presence of others.

Table 76.1 Home Advantage in Team Sports

Sport	Games Studied	Home Team Winning Percentage
Baseball	120,576	55.6%
Cricket	513	57.0
American football	11,708	57.3
Ice hockey	50,739	59.5
Basketball	30,174	62.9
Rugby	2,653	63.7
Soccer	40,380	67.4

Source: From Jeremy Jamieson (2010).

& Schiavo, 1976; Storms & Thomas, 1977). So, for an energetic class or event, choose a room or set up seating that will just barely accommodate everyone.

Social Loafing

Social facilitation experiments test the effect of others' presence on performance on an individual task, such as shooting pool. But what happens to performance when people perform the task as a group? In a team tug-of-war, for example, do you suppose your effort would be more than, less than, or the same as the effort you would exert in a one-on-one tug-of-war? To find out, a University of Massachusetts research team asked blindfolded students "to pull as hard as you can" on a rope. When they fooled the students into believing three others were also pulling behind them, they exerted only 82 percent as much effort as when they thought they were pulling alone (Ingham et al., 1974). And consider what happened when blindfolded people seated in a group clapped or shouted as loud as they could while hearing (through headphones) other people clapping or shouting loudly (Latané, 1981). When they thought they were part of a group effort, the participants produced about one-third less noise than when clapping or shouting "alone."

Working hard, or hardly working?

In group projects, social loafing often occurs, as individuals free ride on the efforts of others.

The point to remember: What you do well, you are likely to do even better in front of an audience, especially a friendly audience. What you normally find difficult may seem all but impossible when you are being watched.

Social facilitation also helps explain a funny effect of crowding. Comedians and actors know that a "good house" is a full one. Crowding triggers arousal, which, as we have seen, strengthens other reactions, too. Comedy routines that are mildly amusing to people in an uncrowded room seem funnier in a densely packed room (Aiello et al., 1983; Freedman & Perlick, 1979). And in experiments, when participants have been seated close to one another, they liked a friendly person even more, an unfriendly person even less (Schiffenbauer

Bibb Latané and his colleagues (1981; Jackson & Williams, 1988) described this diminished effort as **social loafing**. Experiments in the United States, India, Thailand, Japan, China, and Taiwan have recorded social loafing on various tasks, though it was especially common among men in individualist cultures (Karau & Williams, 1993). What causes social loafing? Three things:

- People acting as part of a group feel less accountable, and therefore worry less about what others think.
- Group members may view their individual contributions as dispensable (Harkins & Szymanski, 1989; Kerr & Bruun, 1983).
- When group members share equally in the benefits, regardless of how much they contribute, some may slack off (as you perhaps have observed on group assignments). Unless highly motivated and strongly identified with the group, people may *free ride* on others' efforts.

social loafing the tendency for people in a group to exert less effort when pooling their efforts toward attaining a common goal than when individually accountable.

deindividuation the loss of self-awareness and self-restraint occurring in group situations that foster arousal and anonymity.

Deindividuation

We've seen that the presence of others can arouse people (social facilitation), or it can diminish their feelings of responsibility (social loafing). But sometimes the presence of others does both. The uninhibited behavior that results can range from a food fight to vandalism or rioting. This process of losing self-awareness and self-restraint, called **deindividuation**, often occurs when group participation makes people both *aroused* and *anonymous*. In one experiment, New York University women dressed in depersonalizing Ku Klux Klan-style hoods. Compared with identifiable women in a control group, the hooded women delivered twice as much electric shock to a victim (Zimbardo, 1970). (As in all such experiments, the "victim" did not actually receive the shocks.)

Deindividuation thrives, for better or for worse, in many different settings. Tribal warriors who depersonalize themselves with face paints or masks are more likely than those with exposed faces to kill, torture, or mutilate captured enemies (Watson, 1973). Online, Internet trolls and bullies, who would never say "You're so fake" to someone's face, will hide behind anonymity. Whether in a mob, at a rock concert, at a ballgame, or at worship, when we shed self-awareness and self-restraint, we become more responsive to the group experience—bad or good.

* * *

We have examined the conditions under which being in the *presence* of others can motivate people to exert themselves or tempt them to free ride on the efforts of others, make easy tasks easier and difficult tasks harder, and enhance humor or fuel mob violence. Research also shows that *interacting* with others can similarly have both bad and good effects.

Group Polarization

76-2 What are group polarization and groupthink, and how much power do we have as individuals?

Over time, initial differences between groups of college students tend to grow. If the first-year students at College X tend to be artistic and those at College Y tend to be business-savvy, those differences will probably be even greater by the time they graduate. Similarly, gender differences tend to widen over time, as Eleanor Maccoby (2002) noted from her decades of observing gender development. Girls talk more intimately than boys do and play

Deindividuation During England's 2011 riots and looting, rioters were disinhibited by social arousal and by the anonymity provided by darkness and their hoods and masks. Later, some of those arrested expressed bewilderment over their own behavior.

Figure 76.1

Group polarization If a group is like-minded, discussion strengthens its prevailing opinions. Talking over racial issues increased prejudice in a high-prejudice group of high school students and decreased it in a low-prejudice group (Myers & Bishop, 1970).

and fantasize less aggressively; these differences will be amplified as boys and girls interact mostly with their own gender.

In each case, the beliefs and attitudes we bring to a group grow stronger as we discuss them with like-minded others. This process, called **group polarization**, can have beneficial results, as when it amplifies a sought-after spiritual awareness or reinforces the resolve of those in a self-help group. But it can also have dire consequences. George Bishop and I discovered that when high-prejudice students discussed racial issues, they became *more* prejudiced (**FIGURE 76.1**). (Low-prejudice students became even more accepting.) Thus ideological separation + deliberation = polarization between groups.

Group polarization can feed extremism and even suicide terrorism. Analysis of terrorist organizations around the world reveals that the terrorist mentality does not erupt suddenly, on a whim (McCauley, 2002; McCauley & Segal, 1987; Merari, 2002). It usually begins slowly, among people who share a grievance. As they interact in isolation (sometimes with other “brothers” and “sisters” in camps) their views grow more and more extreme. Increasingly, they categorize the world as “us” against “them” (Moghaddam, 2005; Qirko, 2004). The like-minded echo chamber will continue to polarize people, speculated a 2006 U.S. National Intelligence estimate: “We assess that the operational threat from self-radicalized cells will grow.”

When I got my start in social psychology with experiments on group polarization, I never imagined the potential dangers, or the creative possibilities, of polarization in *virtual* groups. Electronic communication and social networking have created virtual town halls where people can isolate themselves from those whose perspective differs. People read blogs that reinforce their views, and those blogs link to kindred blogs (**FIGURE 76.2**). As the Internet connects the like-minded and pools their ideas, climate-change skeptics, those who believe they’ve been abducted by aliens, and conspiracy theorists find support for their shared ideas and suspicions. White supremacists may become more racist. And militia members may become more terrorism prone. In the echo chambers of virtual worlds, as in the real world, separation + conversation = polarization.

But the Internet-as-social-amplifier can also work for good. Social networking sites connect friends and family members sharing common interests or coping with challenges. Peacemakers, cancer survivors, and bereaved parents can find strength and solace from kindred

group polarization

the enhancement of a group’s prevailing inclinations through discussion within the group.

“What explains the rise of fascism in the 1930s? The emergence of student radicalism in the 1960s? The growth of Islamic terrorism in the 1990s? . . . The unifying theme is simple: *When people find themselves in groups of like-minded types, they are especially likely to move to extremes.* [This] is the phenomenon of group polarization.” -CASS SUNSTEIN, *GOING TO EXTREMES*, 2009

Figure 76.2

Like minds network in the blogosphere Blue liberal blogs link mostly to one another, as do red conservative blogs. (The intervening colors display links across the liberal-conservative boundary.) Each blog’s size reflects the number of other blogs linking to it. (From Lazer et al., 2009.)

Lada Adamic and Natalie Glance. The political blogosphere and the 2004 U.S. election: Divided they blog. In *Proceedings of the 3rd International Workshop on Link Discovery*, pages 36–43, 2005.

spirits. By amplifying shared concerns and ideas, Internet-enhanced communication can also foster social ventures. (I know this personally from social networking with others with hearing loss to transform U. S. assistive-listening technology.)

The point to remember: By linking and magnifying the inclinations of like-minded people, the Internet can be very, very bad, but also very, very good.

Groupthink

So group interaction can influence our personal decisions. Does it ever distort important national decisions? Consider the “Bay of Pigs fiasco.” In 1961, President John F. Kennedy and his advisers decided to invade Cuba with 1400 CIA-trained Cuban exiles. When the invaders were easily captured and soon linked to the U.S. government, Kennedy wondered in hindsight, “How could we have been so stupid?”

Social psychologist Irving Janis (1982) studied the decision-making procedures leading to the ill-fated invasion. He discovered that the soaring morale of the recently elected president and his advisers fostered undue confidence. To preserve the good feeling, group members suppressed or self-censored their dissenting views, especially after President Kennedy voiced his enthusiasm for the scheme. Since no one spoke strongly against the idea, everyone assumed the support was unanimous. To describe this harmonious but unrealistic group thinking, Janis coined the term **groupthink**.

Later studies showed that groupthink—fed by overconfidence, conformity, self-justification, and group polarization—contributed to other fiascos as well. Among them were the failure to anticipate the 1941 Japanese attack on Pearl Harbor; the escalation of the Vietnam war; the U.S. Watergate cover-up; the Chernobyl nuclear reactor accident (Reason, 1987); the U.S. space shuttle *Challenger* explosion (Esser & Lindoerfer, 1989); and the Iraq war, launched on the false idea that Iraq had weapons of mass destruction (U.S. Senate Intelligence Committee, 2004).

Despite the dangers of groupthink, two heads are better than one in solving many problems. Knowing this, Janis also studied instances in which U.S. presidents and their advisers collectively made good decisions, such as when the Truman administration formulated the Marshall Plan, which offered assistance to Europe after World War II, and when the Kennedy administration successfully prevented the Soviets from installing missiles in Cuba. In such instances—and in the business world, too, Janis believed—groupthink is prevented when a leader welcomes various opinions, invites experts’ critiques of developing plans, and assigns people to identify possible problems. Just as the suppression of dissent bends a group toward bad decisions, so open debate often shapes good ones. This is especially so with diverse groups, whose varied perspectives often enable creative or superior outcomes (Nemeth & Ormiston, 2007; Page, 2007). None of us is as smart as all of us.

The Power of Individuals

In affirming the power of social influence, we must not overlook the power of individuals. *Social control* (the power of the situation) and *personal control* (the power of the individual) interact. People aren’t billiard balls. When feeling coerced, we may react by doing the opposite of what is expected, thereby reasserting our sense of freedom (Brehm & Brehm, 1981).

Committed individuals can sway the majority and make social history. Were this not so, communism would have remained an obscure theory, Christianity would be a small Middle Eastern sect, and Rosa Parks’ refusal to sit at the back of the bus would not have ignited the U.S. civil rights movement. Technological history, too, is often made by innovative minorities who overcome the majority’s resistance to change. To many, the railroad was a nonsensical idea; some farmers even feared that train noise would prevent hens from laying eggs. People

“One of the dangers in the White House, based on my reading of history, is that you get wrapped up in groupthink and everybody agrees with everything, and there’s no discussion and there are no dissenting views.” -BARACK OBAMA, DECEMBER 1, 2008, PRESS CONFERENCE

“Truth springs from argument among friends.” -PHILOSOPHER DAVID HUME, 1711–1776

“If you have an apple and I have an apple and we exchange apples then you and I will still each have one apple. But if you have an idea and I have an idea and we exchange these ideas, then each of us will have two ideas.” -ATTRIBUTED TO DRAMATIST GEORGE BERNARD SHAW, 1856–1950

groupthink the mode of thinking that occurs when the desire for harmony in a decision-making group overrides a realistic appraisal of alternatives.

Gandhi As the life of Hindu nationalist and spiritual leader Mahatma Gandhi powerfully testifies, a consistent and persistent minority voice can sometimes sway the majority. Gandhi's nonviolent appeals and fasts were instrumental in winning India's independence from Britain in 1947.

1994). The powers of social influence are enormous, but so are the powers of the committed individual.

Cultural Influences

76-3 How do cultural norms affect our behavior?

Compared with the narrow path taken by flies, fish, and foxes, the road along which environment drives us is wider. The mark of our species—nature's great gift to us—is our ability to learn and adapt. We come equipped with a huge cerebral hard drive ready to receive cultural software.

Culture is the behaviors, ideas, attitudes, values, and traditions shared by a group of people and transmitted from one generation to the next (Brislin, 1988; Cohen, 2009). Human nature, notes Roy Baumeister (2005), seems designed for culture. We are social animals, but more. Wolves are social animals; they live and hunt in packs. Ants are incessantly social, never alone. But “culture is a better way of being social,” notes Baumeister. Wolves function pretty much as they did 10,000 years ago. You and I enjoy things unknown to most of our century-ago ancestors, including electricity, indoor plumbing, antibiotics, and the Internet. Culture works.

Other animals exhibit the rudiments of culture. Primates have local customs of tool use, grooming, and courtship. Younger chimpanzees and macaque monkeys sometimes invent customs—potato washing, in one famous example—and pass them on to their peers and offspring. But human culture does more. It supports our species' survival and reproduction by enabling social and economic systems that give us an edge.

Thanks to our mastery of language, we humans enjoy the *preservation of innovation*. Within the span of this day, I have, thanks to my culture, made good use of Post-it Notes, Google, and digital hearing technology. Moreover, culture enables an efficient *division of labor*. Although one lucky person gets his name on this book's cover, the product actually results from the coordination and commitment of a team of people, no one of whom could produce it alone.

Across cultures, we differ in our language, our monetary systems, our sports, which fork—if any—we eat with, even which side of the road we drive on. But beneath these differences is our great similarity—our capacity for culture. Culture transmits the customs and beliefs that enable us to communicate, to exchange money for things, to play, to eat, and to drive with agreed-upon rules and without crashing into one another.

Variation Across Cultures

We see our adaptability in cultural variations among our beliefs and our values, in how we raise our children and bury our dead, and in what we wear (or whether we wear anything at all). I am ever mindful that the readers of this book are culturally diverse. You and your ancestors reach from Australia to Africa and from Singapore to Sweden.

Riding along with a unified culture is like biking with the wind: As it carries us along, we hardly notice it is there. When we try riding *against* the wind, we feel its force. Face to face with a different culture, we become aware of the cultural winds. Stationed in Iraq, Afghanistan, and Kuwait, American and European soldiers were reminded how liberal their home cultures were.

Humans in varied cultures nevertheless share some basic moral ideas, as we noted earlier. Even before they can walk, babies display a moral sense by showing disapproval of what's wrong or naughty (Bloom, 2010). Yet each cultural group also evolves its own **norms**—rules for accepted and expected behavior. The British have a norm for orderly waiting in line. Many South Asians use only the right hand's fingers for eating. Sometimes social expectations seem oppressive: "Why should it matter how I dress?" Yet, norms grease the social machinery and free us from self-preoccupation.

When cultures collide, their differing norms often befuddle. Should we greet people by shaking hands or kissing each cheek? The answer depends on the surrounding culture. Learning when to clap or bow, how to order at a new restaurant, and what sorts of gestures and compliments are appropriate help us avoid accidental insults and embarrassment.

When we don't understand what's expected or accepted, we may experience *culture shock*. People from Mediterranean cultures have perceived northern Europeans as efficient but cold and preoccupied with punctuality (Triandis, 1981). People from time-conscious Japan—where bank clocks keep exact time, pedestrians walk briskly, and postal clerks fill requests speedily—have found themselves growing impatient when visiting Indonesia, where clocks keep less accurate time and the pace of life is more leisurely (Levine & Norenzayan, 1999). In adjusting to their host countries, the first wave of U.S. Peace Corps volunteers reported that two of their greatest culture shocks, after the language differences, were the differing pace of life and the people's differing sense of punctuality (Spradley & Phillips, 1972).

© The New Yorker Collection, 2010. Harry Bliss from cartoonbank.com. All Rights Reserved

norm an understood rule for accepted and expected behavior. Norms prescribe "proper" behavior.

Variation Over Time

Like biological creatures, cultures vary and compete for resources, and thus evolve over time (Mesoudi, 2009). Consider how rapidly cultures may change. English poet Geoffrey Chaucer (1342–1400) is separated from a modern Briton by only 25 generations, but the two would converse with great difficulty. In the thin slice of history since 1960, most Western cultures have changed with remarkable speed. Middle-class people today fly to places they once only read about. They enjoy the convenience of air-conditioned housing, online shopping, anywhere-anytime electronic communication, and—enriched by doubled per-person real income—eating out more than twice as often as did their grandparents back in the culture of 1960. Many minority groups enjoy expanded human rights. And, with greater economic independence, today's women more often marry for love and less often endure abusive relationships (Circle of Prevention, 2002).

But some changes seem not so wonderfully positive. Had you fallen asleep in the United States in 1960 and awakened today, you would open your eyes to a culture with

more divorce and depression. You would also find North Americans—like their counterparts in Britain, Australia, and New Zealand—spending more hours at work, fewer hours with friends and family, and fewer hours asleep (BLS, 2011; Putnam, 2000).

Whether we love or loathe these changes, we cannot fail to be impressed by their breathtaking speed. And we cannot explain them by changes in the human gene pool, which evolves far too slowly to account for high-speed cultural transformations. Cultures vary. Cultures change. And cultures shape our lives.

Before You Move On

▶ ASK YOURSELF

What two examples of social influence have you experienced this week? (Remember, influence may be informational.)

▶ TEST YOURSELF

You are organizing a Town Hall–style meeting of fiercely competitive political candidates. To add to the fun, friends have suggested handing out masks of the candidates' faces for supporters to wear. What phenomenon might these masks engage?

Answers to the Test Yourself questions can be found in Appendix E at the end of the book.

Module 76 Review

76-1 How is our behavior affected by the presence of others?

- In *social facilitation*, the mere presence of others arouses us, improving our performance on easy or well-learned tasks but decreasing it on difficult ones.
- In *social loafing*, participating in a group project makes us feel less responsible, and we may free ride on others' efforts.
- When the presence of others both arouses us and makes us feel anonymous, we may experience *deindividuation*—loss of self-awareness and self-restraint.

76-2 What are group polarization and groupthink, and how much power do we have as individuals?

- In *group polarization*, group discussions with like-minded others strengthen members' prevailing beliefs and attitudes. Internet communication magnifies this effect, for better and for worse.
- *Groupthink* is driven by a desire for harmony within a decision-making group, overriding realistic appraisal of alternatives.
- The power of the individual and the power of the situation interact. A small minority that consistently expresses its views may sway the majority.

76-3 How do cultural norms affect our behavior?

- A *culture* is a set of behaviors, ideas, attitudes, values, and traditions shared by a group and transmitted from one generation to the next.
- Cultural *norms* are understood rules that inform members of a culture about accepted and expected behaviors.
- Cultures differ across time and space.

Multiple-Choice Questions

1. What do we call the improved performance on simple or well-learned tasks in the presence of others?
 - a. Social facilitation
 - b. Group behavior
 - c. Social loafing
 - d. Deindividuation
 - e. Group polarization
2. Which of the following terms or phrases best describes the behavior of rowdy fans yelling obscenities at a football or soccer referee after a controversial penalty has been called?
 - a. Culture
 - b. Social facilitation
 - c. Groupthink
 - d. Deindividuation
 - e. Group polarization
3. Which of the following is most likely to occur when the desire for harmony in a decision-making group overrides a realistic appraisal of alternatives?
 - a. Group polarization
 - b. Groupthink
 - c. Social loafing
 - d. Norming
 - e. Prejudice
4. What do we call the enduring behaviors, ideas, attitudes, values, and traditions shared by a group of people and transmitted from one generation to the next?
 - a. Deindividuation
 - b. Norms
 - c. Social facilitation
 - d. Culture
 - e. Social control

Practice FRQs

1. Describe the three causes of social loafing.

Answer

1 point: People acting as part of a group feel less accountable.

1 point: Group members may view their individual contributions as dispensable.

1 point: Unless highly motivated and strongly identified with the group, people may free ride on others' efforts.

2. Define groupthink and group polarization. Then, provide an example of each.

(4 points)

Module 77

Prejudice and Discrimination

Module Learning Objectives

77-1 Define *prejudice*, and identify its social and emotional roots.

77-2 Identify the cognitive roots of prejudice.

Paolo Bruno/Getty Images

We have sampled how we *think* about and *influence* one another. Now we come to social psychology's third focus—how we *relate* to one another. What causes us to harm or to help or to fall in love? How can we move a destructive conflict toward a just peace? We will ponder the bad and the good: from prejudice and aggression to attraction, altruism, and peacemaking.

prejudice an unjustifiable and usually negative *attitude* toward a group and its members. Prejudice generally involves stereotyped beliefs, negative feelings, and a predisposition to discriminatory action.

stereotype a generalized (sometimes accurate but often overgeneralized) *belief* about a group of people.

discrimination unjustifiable negative *behavior* toward a group and its members.

Prejudice

77-1 What is *prejudice*? What are its social and emotional roots?

Prejudice means “prejudgment.” It is an unjustifiable and usually negative attitude toward a group—often a different cultural, ethnic, or gender group. Like all attitudes, prejudice is a three-part mixture of

- *beliefs* (in this case, called **stereotypes**).
- *emotions* (for example, hostility or fear).
- predispositions to *action* (to discriminate).

Ethnocentrism—assuming the superiority of one's ethnic group—is one example of prejudice. To *believe* that a person of another ethnicity is somehow inferior or threatening, to *feel* dislike for that person, and to be hesitant to hire or date that person is to be prejudiced. Prejudice is a negative *attitude*. **Discrimination** is a negative *behavior*.

How Prejudiced Are People?

To assess prejudice, we can observe what people say and what they do. Americans' expressed gender and racial attitudes have changed dramatically in the last half-century. The one-third of Americans who in 1937 told Gallup pollsters that they would vote for a qualified woman whom their party nominated for president soared to 89 percent in 2007 (Gallup Brain, 2008; Jones & Moore, 2003). Nearly everyone now agrees that women and men should receive the same pay for the same job, and that children of all races should attend the same schools.

FYI

Percentage of 2010 American marriages to someone whose race or ethnicity differed from one's own:

Whites	9%
Blacks	17%
Hispanics	26%
Asians	28%

Source: Wang, 2012

Support for all forms of racial contact, including interracial dating (**FIGURE 77.1**), has also dramatically increased. Among 18- to 29-year old Americans, 9 in 10 now say they would be fine with a family member marrying someone of a different race (Pew, 2010).

Yet as *overt* prejudice wanes, *subtle* prejudice lingers. Despite increased verbal support for interracial marriage, many people admit that in socially intimate settings (dating, dancing, marrying) they would feel uncomfortable with someone of another race. And many people who *say* they would feel upset with someone making racist slurs actually, when hearing such racism, respond indifferently (Kawakami et al., 2009). In Western Europe, where many “guest workers” and refugees settled at the end of the twentieth century, “modern prejudice”—rejecting immigrant minorities as job applicants for supposedly nonracial reasons—has been replacing blatant prejudice (Jackson et al., 2001; Lester, 2004; Pettigrew, 1998, 2006). A slew of recent experiments illustrates that prejudice can be not only subtle but also automatic and unconscious (see Close-up: Automatic Prejudice on the next page).

Nevertheless, overt prejudice persists in many places. Just ask Italy’s AC Milan soccer star Kevin-Prince Boateng (pictured at the beginning of this module), of Ghanaian descent, who strode off the field in protest after being subjected to racial taunts from spectators. And in the aftermath of the 9/11 terrorist attacks and the Iraq and Afghanistan wars, 4 in 10 Americans acknowledged “some feelings of prejudice against Muslims,” and about half of non-Muslims in Western Europe and the United States perceived Muslims as “violent” (Saad, 2006; Wike & Grim, 2007). With Americans feeling threatened by Arabs, and as opposition to Islamic mosques and immigration flared in 2010, one national observer noted that “Muslims are one of the last minorities in the United States that it is still possible to demean openly” (Kristof, 2010; Lyons et al., 2010). Muslims reciprocated the negativity, with most in Jordan, Egypt, Turkey, and Britain seeing Westerners as “greedy” and “immoral.”

In most places in the world, gays and lesbians cannot comfortably acknowledge who they are and whom they love. Gender prejudice and discrimination persist, too. Despite gender equality in intelligence scores, people have tended to perceive their fathers as more intelligent than their mothers (Furnham & Rawles, 1995). In Saudi Arabia, women are not allowed to drive. In Western countries, we pay more to those (usually men) who care for our streets than to those (usually women) who care for our children. Worldwide, women are more likely to live in poverty (Lipps, 1999), and two-thirds of illiterate adults are women (CIA, 2010).

Unwanted female infants are no longer left out on a hillside to die of exposure, as was the practice in ancient Greece. Yet natural female mortality and the normal male-to-female newborn ratio (105-to-100) hardly explain the world’s estimated 163 million

AP® Exam Tip

It’s worth spending a little time focusing on the distinction between discrimination and prejudice. They are related, but different. The most important thing to note is that prejudice is cognitive in nature. Discrimination, on the other hand, is behavior motivated by prejudice.

“Unhappily, the world has yet to learn how to live with diversity.”
—POPE JOHN PAUL II, ADDRESS TO THE UNITED NATIONS, 1995

Figure 77.1

Prejudice over time Americans’ approval of interracial dating has soared over the past quarter-century (Pew, 2010).

Close-up

Automatic Prejudice

As we have seen throughout this book, the human mind processes thoughts, memories, and attitudes on two different tracks. Sometimes that processing is explicit—on the radar screen of our awareness. To an even greater extent, it is implicit—below the radar, leaving us unaware of how our attitudes are influencing our behavior. Modern studies indicate that prejudice is often implicit, an automatic attitude that is an unthinking knee-jerk response. Consider these findings:

Implicit Racial Associations Using Implicit Association Tests, researchers have demonstrated that even people who deny harboring racial prejudice may carry negative associations (Greenwald et al., 1998, 2009). (By 2011, nearly 5 million people had taken the Implicit Association Test, as you can at www.implicit.harvard.edu.) For example, 9 in 10 White respondents took longer to identify pleasant words (such as *peace* and *paradise*) as “good” when presented with Black-sounding names (such as *Latisha* and *Darnell*) rather than White-sounding names (such as *Katie* and *Ian*). Moreover, people who more quickly associate good things with White names or faces also are the quickest to perceive anger and apparent threat in Black faces (Hugenberg & Bodenhausen, 2003).

Although the test is useful for studying automatic prejudice, critics caution against using it to assess or label individuals (Blanton et al., 2006, 2007, 2009). Defenders counter that implicit biases predict behaviors that range from simple acts of friendliness to the evaluation of work quality (Greenwald et al., 2009). In the 2008 U.S. presidential election, implicit as well as explicit prejudice predicted voters’ support for candidate Barack Obama, whose election in turn served to reduce implicit prejudice (Bernstein et al., 2010; Payne et al., 2010).

Unconscious Patronization When White university women evaluated a flawed essay said to be written by a Black fellow student, they gave markedly higher ratings and never expressed the harsh criticisms they assigned to flawed essays supposedly written by White students (Harber, 1998). Did the evaluators calibrate their evaluations to their racial stereotypes, leading to less exacting standards and a patronizing attitude? In real-world evaluations, such low expectations and the resulting “inflated praise and insufficient criticism” could hinder minority student achievement, the researcher noted. (To preclude such bias, many teachers read essays while “blind” to their authors.)

Race-Influenced Perceptions Our expectations influence our perceptions. In 1999, Amadou Diallo was accosted as he approached his apartment house doorway by police officers looking for a rapist. When he pulled out his wallet, the officers, perceiving a gun, riddled his body with 19 bullets from 41 shots. Curious about

this killing of an unarmed man, two research teams reenacted the situation (Correll et al., 2002, 2007; Greenwald et al., 2003). They asked viewers to press buttons quickly to “shoot” or not shoot men who suddenly appeared on screen. Some of the on-screen men held a gun. Others held a harmless object, such as a flashlight or bottle. People (both Blacks and Whites, in one study) more often shot Black men holding the harmless objects. Priming people with a flashed Black rather than White face also makes them more likely to misperceive a flashed tool as a gun (FIGURE 77.2).

Reflexive Bodily Responses Even people who consciously express little prejudice may give off telltale signals as their body responds selectively to another’s race. Neuroscientists can detect these signals when people look at White and Black faces. The viewers’ implicit prejudice may show up in facial-muscle responses and in the activation of their emotion-processing amygdala (Cunningham et al., 2004; Eberhardt, 2005; Stanley et al., 2008).

If your own gut check reveals you sometimes have feelings you would rather not have about other people, remember this: It is what we do with our feelings that matters. By monitoring our feelings and actions, and by replacing old habits with new ones based on new friendships, we can work to free ourselves from prejudice.

Figure 77.2 Race primes perceptions In experiments by Keith Payne (2006), people viewed (a) a White or Black face, immediately followed by (b) a gun or hand tool, which was then followed by (c) a visual mask. Participants were more likely to misperceive a tool as a gun when it was preceded by a Black rather than White face.

(say that number slowly) “missing women” (Hvistendahl, 2011). In many places, sons are valued more than daughters. With testing that enables sex-selective abortions, several Asian countries have experienced a shortfall in female births (FIGURE 77.3). Although China has declared that sex-selective abortions—gender genocide—are now a criminal offense, the country’s newborn sex ratio is still 118 boys for every 100 girls (Hvistendahl,

Figure 77.3
Missing girls In several Asian countries, especially in China, which has mandated one-child families, boy babies are overrepresented (Abrevaya, 2009). In China, this overrepresentation still occurred in 2009: 54.5 percent of babies were boys and only 45.5 percent were girls (Hvistendahl, 2010).

2009, 2010, 2011), and 95 percent of the children in Chinese orphanages are girls (Webley, 2009). With males under age 20 exceeding females by 32 million, many Chinese bachelors will be unable to find mates (Zhu et al., 2009).

In the United States, a striking sex-ratio bias appears among Chinese, Korean, and Asian Indian parents with a third child. Sons outnumber daughters by 50 percent after two previous girl births. Given a previous boy birth, or given Caucasian parents, there is no sex-ratio bias (Almond & Edlund, 2008).

Studies have shown, however, that most people *feel* more positively about women in general than they do about men (Eagly, 1994; Haddock & Zanna, 1994). Worldwide, people see women as having some traits (such as nurturance, sensitivity, and less aggressiveness) that most people prefer (Glick et al., 2004; Swim, 1994). That may explain why women tend to like women more than men like men (Rudman & Goodwin, 2004). And perhaps that is also why people prefer slightly feminized computer-generated faces—men’s and women’s—to slightly masculinized faces. Researcher David Perrett and his colleagues (1998) have speculated that a slightly feminized male face connotes kindness, cooperativeness, and other traits of a good father. When the British Broadcasting Corporation invited 18,000 women to guess which of the men in **FIGURE 77.4** was most likely to place a personal ad seeking a “special lady to love and cherish forever,” which one do you think they picked?

Figure 77.4
Who do you like best? Which one placed an ad seeking “a special lady to love and cherish forever”? (See answer below.)

Research suggests that subtly feminized features convey a likable image, which people tend to associate more with committed dads than with promiscuous cads. Thus, 66 percent of the women picked computer-generated face (b) in response to both of these questions.

just-world phenomenon

the tendency for people to believe the world is just and that people therefore get what they deserve and deserve what they get.

Social Roots of Prejudice

Why does prejudice arise? Social inequalities and divisions are partly responsible.

SOCIAL INEQUALITIES

When some people have money, power, and prestige and others do not, the "haves" usually develop attitudes that justify things as they are. The **just-world phenomenon** reflects an idea we commonly teach our children—that good is rewarded and evil is punished. From this it is but a short leap to assume that those who succeed must be good and those who suffer must be bad. Such reasoning enables the rich to see both their own wealth and the poor's misfortune as justly deserved.

Are women naturally unassertive and sensitive? This common perception suggests that women are well-suited for the caretaking tasks they have traditionally performed (Hoffman & Hurst, 1990). In an extreme case, slave "owners" perceived slaves as innately lazy, ignorant, and irresponsible—as having the very traits that justified enslaving them. Stereotypes rationalize inequalities.

Victims of discrimination may react with either self-blame or anger (Allport, 1954). Either reaction can feed prejudice through the classic *blame-the-victim* dynamic. Do the circumstances of poverty breed a higher crime rate? If so, that higher crime rate can be used to justify discrimination against those who live in poverty.

US AND THEM: INGROUP AND OUTGROUP

We have inherited our Stone Age ancestors' need to belong, to live and love in groups. There was safety in solidarity (those who didn't band together left fewer descendants). Whether hunting, defending, or attacking, 10 hands were better than 2. Dividing the world into "us" and "them" entails racism and war, but it also provides the benefits of communal solidarity. Thus we cheer for our groups, kill for them, die for them. Indeed, we define who we are partly in terms of our groups. Through our *social identities* we associate ourselves with certain groups and contrast ourselves with others (Hogg, 1996, 2006; Turner, 1987, 2007). When Ian identifies himself as a man, an Aussie, a University of Sydney student, a Catholic, and a MacGregor, he knows who he is, and so do we.

Evolution prepared us, when encountering strangers, to make instant judgments: friend or foe? Those from our group, those who look like us, and also those who *sound* like us—with accents like our own—we instantly tend to like, from childhood onward (Gluszek & Dovidio, 2010; Kinzler et al., 2009). Mentally drawing a circle defines "us," the **ingroup**. But

the social definition of who you are also states who you are not. People outside that circle are "them," the **outgroup**. An **ingroup bias**—a favoring of our own group—soon follows. Even arbitrarily creating us-them groups by tossing a coin creates this bias. In experiments, people have favored their own group when dividing any rewards (Tajfel, 1982; Wilder, 1981).

The urge to distinguish enemies from friends predisposes prejudice against strangers (Whitley, 1999). To Greeks of the classical era, all non-Greeks were "barbarians." In our own era, most students believe their school is better than all other schools in town. Perhaps you can recall being most conscious of your school identity when competing with an archrival school. Many high school students form cliques—jocks, gamers, stoners, theater types, LGBT supporters—and disparage those outside their own group. Even chimpanzees

have been seen to wipe clean the spot where they were touched by a chimpanzee from another group (Goodall, 1986). They also display ingroup empathy, by yawning more after seeing ingroup (rather than outgroup) members yawn (Campbell & de Waal, 2011).

Ingroup bias explains the cognitive power of partisanship (Cooper, 2010; Douthat, 2010). In the United States in the late 1980s, most Democrats believed inflation had risen under Republican president Ronald Reagan (it had dropped). In 2010, most Republicans believed that taxes had increased under Democrat president Barack Obama (for most, they had decreased).

Emotional Roots of Prejudice

Prejudice springs not only from the divisions of society but also from the passions of the heart. **Scapegoat theory** notes that when things go wrong, finding someone to blame can provide a target for anger. Following 9/11, some outraged people lashed out at innocent Arab-Americans. Others called for eliminating Saddam Hussein, the Iraqi leader whom Americans had been grudgingly tolerating. “Fear and anger create aggression, and aggression against citizens of different ethnicity or race creates racism and, in turn, new forms of terrorism,” noted Philip Zimbardo (2001). A decade after 9/11, anti-Muslim animosities still flared, with mosque burnings and efforts to block an Islamic community center near New York City’s Ground Zero.

Evidence for the scapegoat theory of prejudice comes from high prejudice levels among economically frustrated people, and from experiments in which a temporary frustration intensifies prejudice. Students who experience failure or are made to feel insecure often restore their self-esteem by disparaging a rival school or another person (Cialdini & Richardson, 1980; Crocker et al., 1987). To boost our own sense of status, it helps to have others to denigrate. That is why a rival’s misfortune sometimes provides a twinge of pleasure. By contrast, those made to feel loved and supported become more open to and accepting of others who differ (Mikulincer & Shaver, 2001).

Negative emotions nourish prejudice. When facing death, fearing threats, or experiencing frustration, people cling more tightly to their ingroup and their friends. As the terror of death heightens patriotism, it also produces loathing and aggression toward “them”—those who threaten our world (Pyszczynski et al., 2002, 2008). The few individuals who lack fear and its associated amygdala activity—such as children with the genetic disorder Williams syndrome—also display a notable lack of racial stereotypes and prejudice (Santos et al., 2010).

Cognitive Roots of Prejudice

77-2 What are the cognitive roots of prejudice?

Prejudice springs from a culture’s divisions, the heart’s passions, and also from the mind’s natural workings. Stereotyped beliefs are a by-product of how we cognitively simplify the world.

FORMING CATEGORIES

One way we simplify our world is to categorize. A chemist categorizes molecules as organic and inorganic. A football coach categorizes offensive players as quarterbacks, running backs, and wide receivers. Therapists categorize psychological disorders. Human beings categorize people by race, with mixed-race people often assigned to their minority identity. Despite his mixed-race background and being raised by a White mother and White grandparents, Barack Obama has been perceived by White Americans as Black. Researchers believe this happens because, after learning the features of a familiar racial group, the observer’s selective attention is drawn to the distinctive features of the less-familiar minority. Jamin Halberstadt and his colleagues (2011) illustrated this learned-association effect by showing New Zealanders blended Chinese-Caucasian faces. Compared with

“For if [people were] to choose out of all the customs in the world [they would] end by preferring their own.” -GREEK HISTORIAN HERODOTUS, 440 B.C.E.

scapegoat theory the theory that prejudice offers an outlet for anger by providing someone to blame.

“If the Tiber reaches the walls, if the Nile does not rise to the fields, if the sky doesn’t move or the Earth does, if there is famine, if there is plague, the cry is at once: ‘The Christians to the lion!’” -TERTULLIAN, *APologeticus*, 197 C.E.

“The misfortunes of others are the taste of honey.” -JAPANESE SAYING

AP® Exam Tip

Pause for a minute and try to identify examples of the just-world phenomenon, ingroup bias, and scapegoating in your own school. Are there a few or a lot?

Dr. Jamin Halberstadt, Steven J. Sherman, Jeff Sherman, and Gillian Rhodes

Figure 77.5

Categorizing mixed-race people

When New Zealanders quickly classified 104 photos by race, those of European descent more often than those of Chinese descent classified the ambiguous middle two as Chinese (Halberstadt et al., 2011).

participants of Chinese descent, European-descent New Zealanders more readily classified ambiguous faces as Chinese (see **FIGURE 77.5**).

In categorizing people into groups, however, we often stereotype them. We recognize how greatly *we* differ from other individuals in *our* groups. But we overestimate the homogeneity of other groups (we perceive *outgroup homogeneity*). “They”—the members of some other group—seem to look and act alike, while “we” are more diverse (Bothwell et al., 1989). To those in one ethnic group, members of another often seem more alike than they really are in attitudes, personality, and appearance. Our greater recognition for faces of our own race—called the **other-race effect** (also called the *cross-race effect* or *own-race bias*)—emerges during infancy, between 3 and 9 months of age (Gross, 2009; Kelly et al., 2007).

With effort and with experience, people get better at recognizing individual faces from another group (Hugenberg et al., 2010). People of European descent, for example, more accurately identify individual African faces if they have watched a great deal of basketball on television, exposing them to many African-heritage faces (Li et al., 1996). And the longer Chinese people have resided in a Western country, the less they exhibit the other-race effect (Hancock & Rhodes, 2008).

REMEMBERING VIVID CASES

As we saw in Module 35’s discussion of the availability heuristic, we often judge the frequency of events by instances that readily come to mind. In a classic experiment, researchers showed two groups of University of Oregon students lists containing information about 50 men (Rothbart et al., 1978). The first group’s list included 10 men arrested for *nonviolent* crimes, such as forgery. The second group’s list included 10 men arrested for *violent* crimes, such as assault. Later, both groups were asked how many men on their list had committed *any* sort of crime. The second group overestimated the number. Vivid (violent) cases are more readily available to our memory and feed our stereotypes (**FIGURE 77.6**).

BELIEVING THE WORLD IS JUST

As we noted earlier, people often justify their prejudices by blaming victims. If the world is just, “people must get what they deserve.” As one German civilian is said to have remarked when visiting the Bergen-Belsen concentration camp shortly after World War II, “What terrible criminals these prisoners must have been to receive such treatment.”

© Dave Coverly

other-race effect the tendency to recall faces of one’s own race more accurately than faces of other races. Also called the *cross-race effect* or the *own-race bias*.

Figure 77.6

Vivid cases feed stereotypes The 9/11 Muslim terrorists created, in many minds, an exaggerated stereotype of Muslims as terrorism prone. Actually, reported a U.S. National Research Council panel on terrorism, when offering this inexact illustration, most terrorists are not Muslim and “the vast majority of Islamic people have no connection with and do not sympathize with terrorism” (Smelser & Mitchell, 2002).

Hindsight bias is also at work here (Carli & Leonard, 1989). Have you ever heard people say that rape victims, abused spouses, or people with AIDS got what they deserved? In some countries, such as Pakistan, women who have been raped have sometimes been sentenced to severe punishment for having violated a law against adultery (Mydans, 2002). In one experiment illustrating the blame-the-victim phenomenon, people were given a detailed account of a date that ended with the woman being raped (Janoff-Bulman et al., 1985). They perceived the woman's behavior as at least partly to blame, and in hindsight, they thought, "She should have known better." (Blaming the victim also serves to reassure people that it couldn't happen to them.) Others, given the same account with the rape ending deleted, did not perceive the woman's behavior as inviting rape.

People also have a basic tendency to justify their culture's social systems (Jost et al., 2009; Kay et al, 2009). We're inclined to see the way things are as the way they ought to be. This natural conservatism makes it difficult to legislate major social changes, such as health care or climate-change policies. Once such policies are in place, our "system justification" tends to preserve them.

Before You Move On

▶ ASK YOURSELF

What are some examples of ingroup bias in your community?

▶ TEST YOURSELF

What is the difference between prejudice and discrimination?

Answers to the Test Yourself questions can be found in Appendix E at the end of the book.

Module 77 Review

77-1

What is *prejudice*? What are its social and emotional roots?

- *Prejudice* is an unjustifiable, usually negative attitude toward a group and its members.
- Prejudice's three components are beliefs (often *stereotypes*), emotions, and predispositions to action (*discrimination*).
- Overt prejudice in North America has decreased over time, but implicit prejudice—an automatic, unthinking attitude—continues.
- The social roots of prejudice include social inequalities and divisions.
 - Higher-status groups often justify their privileged position with the *just-world phenomenon*.
 - We tend to favor our own group (*ingroup bias*) as we divide ourselves into "us" (the *ingroup*) and "them" (the *outgroup*).
- Prejudice can also be a tool for protecting our emotional well-being, as when we focus our anger by blaming events on a *scapegoat*.

77-2

What are the cognitive roots of prejudice?

- The cognitive roots of prejudice grow from our natural ways of processing information: forming categories, remembering vivid cases, and believing that the world is just and our own and our culture's ways of doing things are the right ways.

Multiple-Choice Questions

- Which of the following is the primary distinction between prejudice and discrimination?
 - Prejudice is cognitive and discrimination is behavioral.
 - Prejudice is based on anger and discrimination is based on fear.
 - Prejudice is a legal term and discrimination is a psychological term.
 - Discrimination typically develops in infancy and prejudice typically develops in adolescence.
 - Discrimination is primarily caused by nature and prejudice is primarily caused by nurture.
- Which of the following is true of prejudice in recent years?
 - Both overt and subtle prejudice have shown steady and equal increases.
 - Subtle prejudice has been decreasing more than overt prejudice.
 - Both overt and subtle prejudice have been increasing, but overt prejudice is increasing at a faster rate.
 - Both overt and subtle prejudice have been increasing, but subtle prejudice is increasing at a faster rate.
 - Overt prejudice has been decreasing more than subtle prejudice.
- Which of the following accurately describes the just-world phenomenon?
 - It's the reduction in prejudice that has resulted from improvements in our laws and judicial system.
 - It's the reduction in discrimination that has resulted from improvements in our laws and judicial system.
 - It's the belief that most people get what they deserve and deserve what they get.
 - It's the tendency of people to deny that prejudice is still a problem.
 - It's our mind's desire to categorize daily events as either "fair" or "unfair."
- Which of the following is an example of ingroup bias?
 - Hinata talked only to her five best friends when she was in ninth grade.
 - Sabrina has been a New York Yankee fan since she was in fourth grade.
 - Kimia believes she is the best student in her AP[®] Psychology class, but her grades are not as good as several students.
 - Francisco believes he is the best student in his AP[®] Psychology class, and in fact he has the highest test average.
 - Derek believes his t-ball team is the best in the league.
- A member of one racial group viciously beats someone from a different racial group. The incident is widely publicized in the local media. Which of the following terms best describes this incident?
 - Scapegoat theory
 - Vivid case
 - Just-world phenomenon
 - Other-race effect
 - Ingroup bias

Practice FRQs

- Describe the three major components of prejudice.

Answer

1 point: Stereotyped judgments, which are generalized, negative beliefs about a group of people.

1 point: Negative emotions, such as hostility or fear, toward the members of a group.

1 point: A predisposition to discriminate against members of a group.

- Describe an example of a social root of prejudice, an emotional root of prejudice, and a cognitive root of prejudice.

(3 points)

Module 78

Aggression

Module Learning Objectives

78-1 Explain how psychology's definition of *aggression* differs from everyday usage, and identify the biological factors that make us more prone to hurt one another.

78-2 Outline psychological and social-cultural triggers of aggression.

78-1 How does psychology's definition of *aggression* differ from everyday usage? What biological factors make us more prone to hurt one another?

Prejudice hurts, but aggression often hurts more. In psychology, **aggression** is any physical or verbal behavior intended to hurt or destroy, whether done out of hostility or as a calculated means to an end. The assertive, persistent salesperson is not aggressive. Nor is the dentist who makes you wince with pain. But the person who passes along a vicious rumor about you, the person who verbally assaults you, and the attacker who mugs you for your money are aggressive.

Aggressive behavior emerges from the interaction of biology and experience. For a gun to fire, the trigger must be pulled; with some people, as with hair-trigger guns, it doesn't take much to trip an explosion. Let's look first at some biological factors that influence our thresholds for aggressive behavior, then at the psychological factors that pull the trigger.

The Biology of Aggression

Aggression varies too widely from culture to culture, era to era, and person to person to be considered an unlearned instinct. But biology does *influence* aggression. We can look for biological influences at three levels—genetic, neural, and biochemical.

Genetic Influences

Genes influence aggression. We know this because animals have been bred for aggressiveness—sometimes for sport, sometimes for research. The effect of genes also appears in human twin studies (Miles & Carey, 1997; Rowe et al., 1999). If one identical twin admits to “having a violent temper,” the other twin will often independently admit the same. Fraternal twins are much less likely to respond similarly. Researchers continue to search for genetic markers in those who commit the most violence. (One is already well known and is carried by half the human race: the Y chromosome.)

aggression any physical or verbal behavior intended to hurt or destroy.

FYI

In the last 40 years in the United States, well over 1 million people—more than all deaths in all wars in American history—have been killed by firearms in nonwar settings. Compared with people of the same sex, race, age, and neighborhood, those who keep a gun in the home (ironically, often for protection) are almost three times more likely to be murdered in the home—nearly always by a family member or close acquaintance. For every self-defense use of a gun in the home, there have been 4 unintentional shootings, 7 criminal assaults or homicides, and 11 attempted or completed suicides (Kellermann et al., 1993, 1997, 1998; see also Branas et al., 2009).

AP® Exam Tip

Notice that you're back to a nature and nurture analysis again. The biology section is, of course, the nature component. When you get to the psychological and social-cultural factors coming up, that's nurture.

"It's a guy thing."

Neural Influences

There is no one spot in the brain that controls aggression. Aggression is a complex behavior, and it occurs in particular contexts. But animal and human brains have neural systems that, given provocation, will either inhibit or facilitate aggressive behavior (Denson, 2011; Moyer, 1983). Consider:

- Researchers implanted a radio-controlled electrode in the brain of the domineering leader of a caged monkey colony. The electrode was in an area that, when stimulated, inhibits aggression. When researchers placed the control button for the electrode in the colony's cage, one small monkey learned to push it every time the boss became threatening.
- A neurosurgeon, seeking to diagnose a disorder, implanted an electrode in the amygdala of a mild-mannered woman. Because the brain has no sensory receptors, she was unable to feel the stimulation. But at the flick of a switch she snarled, "Take my blood pressure. Take it now," then stood up and began to strike the doctor.
- Studies of violent criminals have revealed diminished activity in the frontal lobes, which play an important role in controlling impulses. If the frontal lobes are damaged, inactive, disconnected, or not yet fully mature, aggression may be more likely (Amen et al., 1996; Davidson et al., 2000; Raine, 1999, 2005).

Biochemical Influences

Our genes engineer our individual nervous systems, which operate electrochemically. The hormone testosterone, for example, circulates in the bloodstream and influences the neural systems that control aggression. A raging bull will become a gentle Ferdinand when castration reduces its testosterone level. The same is true of mice. When injected with testosterone, gentle, castrated mice once again become aggressive.

Humans are less sensitive to hormonal changes. But as men age, their testosterone levels—and their aggressiveness—diminish. Hormonally charged, aggressive 17-year-olds mature into hormonally quieter and gentler 70-year-olds. Also, violent criminals tend to be muscular young males with higher-than-average testosterone levels, lower-than-average intelligence scores, and low levels of the neurotransmitter serotonin (Dabbs et al., 2001a; Pendick, 1994). Men more than women tend to have wide faces, a testosterone-linked trait, rather than roundish or long faces. And men's facial width is a predictor of their aggressiveness (Carré et al., 2009; Stirrat & Perrett, 2010).

High testosterone correlates with irritability, assertiveness, impulsiveness, and low tolerance for frustration—qualities that predispose somewhat more aggressive responses to provocation or competition for status (Dabbs et al., 2001b; Harris, 1999; McAndrew, 2009). Among both teenage boys and adult men, high testosterone levels correlate with delinquency, hard drug use, and aggressive-bullying responses to frustration (Berman et al., 1993; Dabbs & Morris, 1990; Olweus et al., 1988). Drugs that sharply reduce testosterone levels subdue men's aggressive tendencies.

"We could avoid two-thirds of all crime simply by putting all able-bodied young men in cryogenic sleep from the age of 12 through 28." -DAVID T. LYKKEN, *THE ANTISOCIAL PERSONALITIES*, 1995

A lean, mean fighting machine—the testosterone-laden female hyena The hyena's unusual embryology pumps testosterone into female fetuses. The result is revved-up young female hyenas who seem born to fight.

Another drug that sometimes circulates in the bloodstream—alcohol—*unleashes* aggressive responses to frustration. In police data and prison surveys, as in experiments, aggression-prone people are more likely to drink, and they are more likely to become violent when intoxicated (White et al., 1993). People who have been drinking commit 4 in 10 violent crimes and 3 in 4 acts of spousal abuse (Karberg & James, 2005). Alcohol's effects are both biological and psychological (Bushman, 1993; Ito et al., 1996; Taylor & Chermack, 1993). Those who only *think* they've imbibed alcohol will be somewhat affected, but so, too, will those who have had alcohol unknowingly slipped into a drink. Unless people are distracted, alcohol tends to focus their attention on a provocation rather than on inhibitory cues (Giancola & Corman, 2007). Alcohol also inclines people to interpret ambiguous acts (such as a bump in a crowd) as provocations (Bègue et al., 2010).

Psychological and Social-Cultural Factors in Aggression

78-2 What psychological and social-cultural factors may trigger aggressive behavior?

Biological factors influence the ease with which aggression is triggered. But what psychological and social-cultural factors pull the trigger?

Aversive Events

Suffering sometimes builds character. In laboratory experiments, however, those made miserable have often made others miserable (Berkowitz, 1983, 1989). This phenomenon is called the **frustration-aggression principle**: Frustration creates anger, which can spark aggression. One analysis of 27,667 hit-by-pitch Major League Baseball incidents between 1960 and 2004 revealed this link (Timmerman, 2007). Pitchers were most likely to hit batters when

- they had been frustrated by the previous batter hitting a home run.
- the current batter had hit a home run the last time at bat.
- a teammate had been hit by a pitch in the previous half-inning.

Other aversive stimuli—hot temperatures, physical pain, personal insults, foul odors, cigarette smoke, crowding, and a host of others—can also evoke hostility. In laboratory experiments, when people get overheated, they think, feel, and act more aggressively. In baseball games, the number of hit batters rises with the temperature (Reifman et al., 1991; see **FIGURE 78.1**). And in the wider world, violent crime and spousal abuse rates have been higher during hotter years, seasons, months, and days (Anderson & Anderson, 1984).

frustration-aggression principle
the principle that frustration—the blocking of an attempt to achieve some goal—creates anger, which can generate aggression.

Figure 78.1
Temperature and retaliation

Richard Larrick and his colleagues (2011) looked for occurrences of batters hit by pitchers during 4,566,468 pitcher-batter matchups across 57,293 Major League Baseball games since 1952. The probability of a hit batter increased if one or more of the pitcher's teammates had been hit, and also with temperature.

From the available data, Craig Anderson and his colleagues (2000; 2011) have projected that, other things being equal, global warming of 4 degrees Fahrenheit (about 2 degrees centigrade) would induce tens of thousands of additional assaults and murders—and that’s before the added violence inducement from climate-change-related drought, poverty, food insecurity, and migration.

AP® Exam Tip

David Myers points out that this section is an application of material that was introduced in Unit VI. You should go back there for a quick review if you don’t recognize the basic components of operant conditioning and observational learning in this material.

Reinforcement and Modeling

Aggression may be a natural response to aversive events, but learning can alter natural reactions. As Unit VI explained, we learn when our behavior is reinforced, and we learn by watching others.

In situations where experience has taught us that aggression pays, we are likely to act aggressively again. Children whose aggression has successfully intimidated other children may become bullies. Animals that have successfully fought to get food or mates become increasingly ferocious. To foster a kinder, gentler world we had best model and reward sensitivity and cooperation from an early age, perhaps by training parents to discipline without modeling violence.

Parents of delinquent youth frequently cave in to (reward) their children’s tears and temper tantrums. Then, exasperated, they discipline with beatings (Patterson et al., 1982, 1992).

Parent-training programs often advise parents to avoid modeling violence by screaming and hitting. Instead, parents should reinforce desirable behaviors and frame statements positively. (“When you finish loading the dishwasher you can go play,” rather than “If you don’t load the dishwasher, there’ll be no playing.”)

One *aggression-replacement program* worked with juvenile offenders and gang members and their parents. It taught both generations new ways to control anger, and more thoughtful approaches to moral reasoning (Goldstein et al., 1998). The result? The youths’ re-arrest rates dropped.

Different cultures model, reinforce, and evoke different tendencies toward violence. For example, crime rates are higher (and average happiness is lower) in countries marked by a great disparity between rich and poor (Triandis, 1994). In the United States, cultures and families that experience minimal father care also have high violence rates (Triandis, 1994). Even after controlling for parental education, race, income, and teen motherhood, American male youths from father-absent homes have double their peers’ incarceration rate (Harper & McLanahan, 2004).

Violence can also vary by culture within a country. Richard Nisbett and Dov Cohen (1996) analyzed violence among White Americans in southern towns settled by Scots-Irish herders whose tradition emphasized “manly honor,” the use of arms to protect one’s flock, and a history of coercive slavery. Compared with their White counterparts in New England towns settled by the more traditionally peaceful Puritan, Quaker, and Dutch farmer-artisans, the cultural descendants of those herders have triple the homicide rates and are more supportive of physically punishing children, of warfare initiatives, and of uncontrolled gun ownership. “Culture-of-honor” states also have higher rates of students bringing weapons to school and of school shootings (Brown et al., 2009).

Media Models for Violence

Parents are hardly the only aggression models. In the United States and elsewhere, TV shows, films, video games, and YouTube offer supersized portions of violence. Repeatedly viewing on-screen violence teaches us **social scripts**—culturally provided mental files for how to act. When we find ourselves in new situations, uncertain how to behave, we rely on social scripts. After so many action films, teens may acquire a script that plays in their head when they face real-life conflicts. Challenged, they may “act like a man” by intimidating or eliminating the threat. Likewise, after viewing the multiple sexual innuendoes and acts found in most prime-time TV shows—often involving impulsive or short-term relationships—youths may acquire sexual scripts they later enact in real-life relationships (Kunkel et al., 2001; Sapolsky & Tabarlet, 1991).

social script culturally modeled guide for how to act in various situations.

Music lyrics also write social scripts. In one set of experiments, German university men administered hotter chili sauce to a woman and recalled more negative feelings and beliefs about women after listening to woman-hating song lyrics. Man-hating song lyrics had a similar effect on the aggressive behavior of women listeners (Fischer & Greitemeyer, 2006).

Sexual aggression is sometimes modeled in X-rated films and pornography. Content analyses have revealed that most X-rated films depict quick, casual sex between strangers, but sometimes also provide scenes of rape and sexual exploitation of women by men (Cow-an et al., 1988; NCTV, 1987; Yang & Linz, 1990). These scenes often include enactments of the *rape myth*—the idea that some women invite or enjoy rape and get “swept away” while being “taken.” (In actuality, rape is traumatic, and it frequently harms women’s reproductive and psychological health [Golding, 1996].) Most rapists accept this myth (Brinson, 1992). So do many men and women who watch a great deal of TV: Compared with those who watch little television, heavy viewers are more accepting of the rape myth (Kahlor & Morrison, 2007). Might sexually explicit media models in the \$97 billion global pornography business contribute to sexually aggressive tendencies (D’Orlando, 2011)?

Most consumers of child and adult pornography commit no known sexual crimes (Seto, 2009). But they are more likely to accept the rape myth as reality (Kingston et al., 2009). Canadian and U.S. sex offenders acknowledge a greater-than-usual appetite for sexually explicit and sexually violent materials—materials typically labeled as pornography (Kingston et al., 2009; Marshall, 1989, 2000; Oddone-Paolucci et al., 2000). The Los Angeles Police Department, for example, reported that pornography was “conspicuously present” in 62 percent of its extrafamilial child sexual abuse cases during the 1980s (Bennett, 1991). High pornography consumption also has predicted greater sexual aggressiveness among university men, even after controlling for other predictors of antisocial behavior (Vega & Malamuth, 2007). But critics object. Since 1990, the reported U.S. rape rate has declined while pornography consumption has increased (Ferguson & Hartley, 2009). And aren’t many sexual aggressors merely, as sex researcher John Money (1988) suspected, using pornography “as an alibi to explain to themselves what otherwise is inexplicable”?

People heavily exposed to televised crime see the world as more dangerous. People heavily exposed to pornography see the world as more sexual. Repeatedly watching X-rated films, even nonviolent films, has many effects (Kingston et al., 2009). One’s own partner seems less attractive (Module 39). Extramarital sex seems less troubling (Zillmann, 1989). A woman’s friendliness seems more sexual. Sexual aggression seems less serious (Harris, 1994; Zillmann, 1989). These effects feed the ingredients of coercion against women.

In one experiment, undergraduates viewed six brief, sexually explicit films each week for six weeks (Zillmann & Bryant, 1984). A control group viewed nonerotic films during the same six-week period. Three weeks later, both groups read a newspaper report about a man convicted but not yet sentenced for raping a hitchhiker. When asked to suggest an appropriate prison term, viewers of the sexually explicit films recommended sentences half as long as those recommended by the control group.

Experiments cannot elicit actual sexual violence, but they can assess a man’s willingness to hurt a woman. Often the research gauges the effect of violent versus nonviolent erotic films on men’s willingness to deliver supposed electric shocks to women who had earlier provoked them. These experiments suggest that it’s less the eroticism than the depictions of sexual *violence* (whether in R-rated slasher films or X-rated films) that most directly affect men’s acceptance and performance of aggression against women.

To a lesser extent, nonviolent pornography can also influence aggression. In a series of studies, Nathaniel Lambert and his colleagues (2011) used various methods to explore pornography’s effects on aggression against relationship partners. They found that pornography consumption predicted both self-reported aggression and laboratory noise blasts to their partner, and that abstaining from customary pornography consumption decreased aggression (while abstaining from their favorite food did not).

AP® Exam Tip

In the experiment described here, can you identify the independent and dependent variables? It’s great practice to do this every time you read about an experiment.

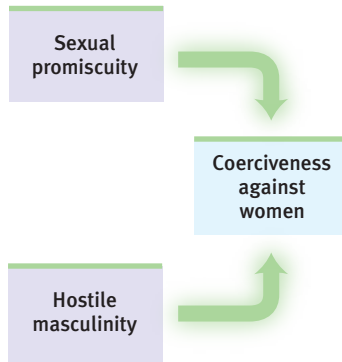

Figure 78.2

Men who sexually coerce women

The recipe for coercion against women combines an impersonal approach to sex with a hostile masculinity. (Adapted from Malamuth, 1996.)

Coincidence or cause? In 2011, Norwegian Anders Behring Breivik bombed government buildings in Oslo, and then went to a youth camp where he shot and killed 69 people, mostly teens. As a player of first-person shooter games, Breivik stirred debate when he commented that “I see *MW2* [*Modern Warfare 2*] more as a part of my training-simulation than anything else.” Did his violent game playing contribute to his violence, or was it a mere coincidental association? To explore such questions, psychologists experiment.

Neil Malamuth (1996) has shown that sexually coercive men typically are sexually promiscuous and hostile in their relationships with women (**FIGURE 78.2**). Several factors can create a predisposition to sexual violence (Malamuth et al., 1991, 1995). They include media influences but also dominance motives, disinhibition by alcohol, and a history of child abuse. Still, media depictions of violence can disinhibit and desensitize; viewing sexual violence fosters hostile, domineering attitudes and behaviors; and viewing pornography leads viewers to trivialize rape, devalue their partners, and engage in uncommitted sex. Media influence is not a minor issue.

Might public consciousness be raised by making people aware of the information you have just been reading? In the 1940s, movies often depicted African-Americans as childlike, superstitious buffoons, images we would not tolerate today. Many hope that entertainers, producers, and audiences might someday look back with embarrassment on the days when movies “entertained” us with scenes of sexual coercion, torture, and mutilation.

Do Violent Video Games Teach Social Scripts for Violence?

Violent video games became an issue for public debate after teenagers in more than a dozen places seemed to mimic the carnage in the shooter games they had so often played (Anderson, 2004a). In 2002, two Grand Rapids, Michigan, teens and a man in his early twenties spent part of a night drinking beer and playing *Grand Theft Auto III*. Using simulated cars, they ran down pedestrians, then beat them with fists, leaving a bloody body behind (Kolker, 2002). The same teens and man then went out for a real drive. Spotting a 38-year-old man on a bicycle, they ran him down with their car, got out, stomped and punched him, and returned home to play the game some more. (The victim, a father of three, died six days later.)

As we noted in Module 30, observing media violence tends to desensitize people to cruelty and prime them to respond aggressively when provoked. Does this violence-viewing effect extend to playing violent video games? Should parents worry about the ways actively role-playing aggression will affect their children? Experiments indicate that playing positive games has positive effects. For example, playing *Lemmings*, where a goal is to help others, increases real-life helping (Greitemeyer & Osswald, 2010). So, might a parallel effect occur after playing games that enact violence?

When combining data from 400 studies with 130,296 participants, Craig Anderson and his colleagues (2010) found such an effect: Playing violent video games increased aggression. The finding held for youth and for young adults; in North America, Japan, and Western Europe; and with each of three major research designs (correlational, experimental, and longitudinal). In a 2010 statement submitted for a U.S. Supreme Court case, Anderson was joined by more than 100 social scientists in explaining that “the psychological processes underlying such effects are well understood and include: imitation; observational learning; priming of cognitive, emotional, and behavioral scripts; physiological arousal; and emotional desensitization.”

Consider some evidence:

- University men who spent the most hours playing violent video games tended to be the most physically aggressive (for example, more likely to acknowledge having hit or attacked someone else) (Anderson & Dill, 2000).
- People randomly assigned to play a game involving bloody murders with groaning victims (rather than to play nonviolent *Myst*) became more hostile. On a follow-up task, they also were more likely to blast intense noise at a fellow student.
- People with extensive experience in violent video gaming display desensitization to violence, as shown by blunted brain responses; they also are less likely to help an injured victim (Bartholow et al., 2006; Bushman & Anderson, 2009).
- After playing a violent rather than a neutral or prosocial video game, people become more likely to express dehumanized perceptions of immigrant outgroups (Greitemeyer & McLatchie, 2011).

Young adolescents who play a lot of violent video games see the world as more hostile. Compared with nongaming kids, they get into more arguments and fights and get worse grades (Gentile, 2009). Ah, but is this merely because naturally hostile kids are drawn to such games? Apparently not. Comparisons of gamers and nongamers who scored low in hostility revealed a difference in the number of reported fights: 38 percent of the violent-game players had been in fights, versus only 4 percent of the nongamers. Over time, the nongamers became more likely to have fights only if they started playing the violent games (Anderson, 2004a). Another study, with German adolescents, found that today's violent game playing predicts future aggression, but today's aggression does not predict future game playing (Möller & Krahé, 2008). Some researchers believe that, due partly to the more active participation and rewarded violence of game play, violent video games have even greater effects on aggressive behavior and cognition than do violent TV shows and movies (Anderson et al., 2007). The effects of violent gaming, some say, are comparable to the toxic effects of asbestos or second-hand smoke exposure (Bushman et al., 2010). "Playing violent video games probably will not turn your child into a psychopathic killer," acknowledges researcher Brad Bushman (2011), "but I would want to know how the child treats his or her parents, how they treat their siblings, how much compassion they have."

Others are unimpressed by violent-game-effect findings (Ferguson & Kilburn, 2010). They note that from 1996 to 2006, youth violence was declining while video game sales were increasing. Moreover, some point out that avid game players are quick and sharp: they develop speedy reaction times and enhanced visual skills (Dye et al., 2009; Green et al., 2010). The focused fun of game playing can satisfy basic needs for a sense of competence, control, and social connection (Przbylski et al., 2010). That helps explain why, in one experiment, elementary school boys randomly selected to receive a game system spent enormous amounts of time on it over the next four months, with diminished time spent on schoolwork and with more academic problems (Weis & Cerankosky, 2010).

This much seems clear. Aggressive thoughts can lead to violent behavior and role playing can increase aggressive thoughts and emotions. As the Greek philosopher Aristotle observed, "We are what we repeatedly do."

Nevertheless, a 2011 Supreme Court decision overturned a California state law that banned violent video game sales to children (much like the ban on sales of sexually explicit materials to children). The First Amendment's free speech guarantee protects even offensive games, said the court's majority, which was unpersuaded by the evidence of harm. But the debate goes on. "What sense does it make to forbid selling to a 13-year-old a magazine with an image of a nude woman," wrote Justice Stephen Breyer, in a dissenting opinion, "while protecting the sale to that 13-year-old of an interactive video game in which he actively, but virtually, binds and gags the woman, then tortures and kills her?"

* * *

To sum up, significant behaviors, such as violence, usually have many determinants, making any single explanation an oversimplification. Asking what causes violence is therefore like asking what causes cancer. Asbestos exposure, for example, is indeed a cancer cause, albeit only one among many. Research reveals many different biological, psychological, and social-cultural influences on aggressive behavior. Like so much else, aggression is a biopsychosocial phenomenon (**FIGURE 78.3**).

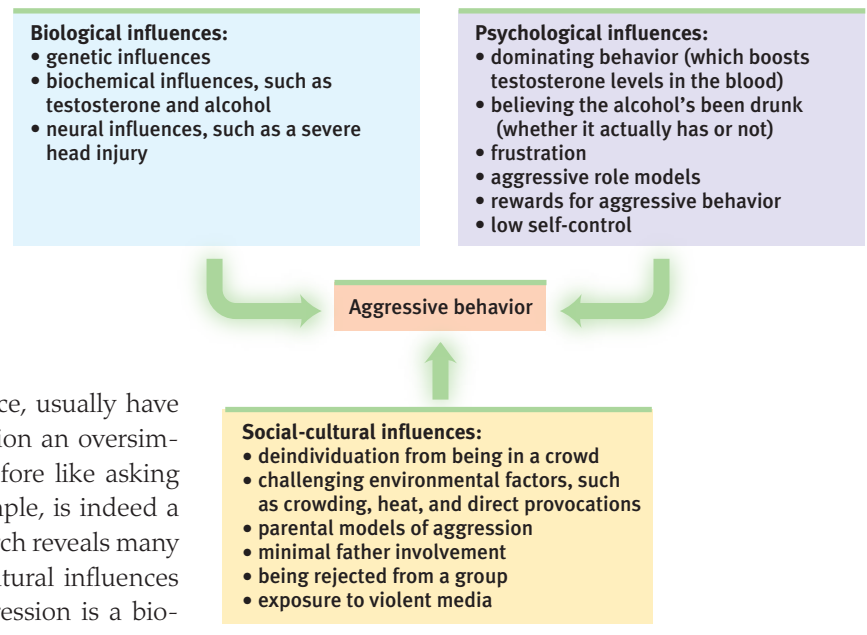

Figure 78.3

Biopsychosocial understanding of aggression

Because many factors contribute to aggressive behavior, there are many ways to change such behavior, including learning anger management and communication skills, and avoiding violent media and video games.

It is also important to note that many people are leading gentle, even heroic lives amid personal and social stresses, reminding us again that individuals differ. The person matters. That people vary over time and place reminds us that environments also differ. Yesterday's plundering Vikings have become today's peace-promoting Scandinavians. Situations matter. Like all behavior, aggression arises from the interaction of persons and situations.

Before You Move On

▶ ASK YOURSELF

Do you think there should be laws to prevent children's exposure to violent media? Why or why not?

▶ TEST YOURSELF

What psychological, biological, and social-cultural influences interact to produce aggressive behaviors?

Answers to the Test Yourself questions can be found in Appendix E at the end of the book.

Module 78 Review

78-1

How does psychology's definition of *aggression* differ from everyday usage? What biological factors make us more prone to hurt one another?

- In psychology, *aggression* is any physical or verbal behavior intended to hurt or destroy.
- Biology influences our threshold for aggressive behaviors at three levels: genetic (inherited traits), neural (activity in key brain areas), and biochemical (such as alcohol or excess testosterone in the bloodstream).
- Aggression is a complex behavior resulting from the interaction of biology and experience.

78-2

What psychological and social-cultural factors may trigger aggressive behavior?

- Frustration (*frustration-aggression principle*), previous reinforcement for aggressive behavior, and observing an aggressive role model can all contribute to aggression.
 - Media portrayals of violence provide *social scripts* that children learn to follow.
 - Viewing sexual violence contributes to greater aggression toward women.
 - Playing violent video games increases aggressive thoughts, emotions, and behaviors.

Multiple-Choice Questions

1. A friend fails to meet an achievement goal. As a result, he gets angry and behaves aggressively. Which of the following terms best identifies this chain of events?
 - a. Aggression
 - b. Fundamental attribution error
 - c. Frustration-aggression principle
 - d. Social scripts
 - e. Biopsychosocial hypothesis
2. What do we call culturally modeled guides for how to act in various situations?
 - a. Aggressive behavior
 - b. Cultures of honor
 - c. Reinforcement modeling
 - d. Social scripts
 - e. Social-cultural influences
3. Which of the following is an example of a social-cultural influence on aggressive behavior?
 - a. Exposure to violent media
 - b. Frustration
 - c. Testosterone
 - d. Believing you've drunk alcohol
 - e. Genetics

Practice FRQs

1. Using the biopsychosocial model, give a biological influence, social-cultural influence, and a psychological influence on aggressive behavior.
2. Define social scripts and the frustration-aggression principle. Then, provide an example of each.

(4 points)

Answer

1 point: Biological: genetics, biochemicals (for example, testosterone), or neural (for example, severe frontal lobe injury).

1 point: Social-cultural: exposure to violent media, rejection from a group, or parental models of aggression.

1 point: Psychological: frustration, aggressive role models, or rewards for aggressive behavior.

Module 79

Attraction

Module Learning Objectives

- 79-1** Explain why we befriend or fall in love with some people but not others.
- 79-2** Describe how romantic love typically changes as time passes.

mere exposure effect

the phenomenon that repeated exposure to novel stimuli increases liking of them.

AP® Exam Tip

Can you remember the other use of the term *proximity* earlier in the course? It's one of the Gestalt principles from Unit IV, Sensation and Perception.

Pause a moment and think about your relationships with two people—a close friend, and someone who has stirred your feelings of romantic love. What psychological chemistry binds us together in these special sorts of attachments that help us cope with all other relationships? Social psychology suggests some answers.

The Psychology of Attraction

- 79-1** Why do we befriend or fall in love with some people but not others?

We endlessly wonder how we can win others' affection and what makes our own affections flourish or fade. Does familiarity breed contempt, or does it intensify affection? Do birds of a feather flock together, or do opposites attract? Is beauty only skin deep, or does attractiveness matter greatly? To explore these questions, let's consider three ingredients of our liking for one another: proximity, attractiveness, and similarity.

Proximity

Before friendships become close, they must begin. *Proximity*—geographic nearness—is friendship's most powerful predictor. Proximity provides opportunities for aggression, but much more often it breeds liking. Study after study reveals that people are most inclined to like, and even to marry, those who live in the same neighborhood, who sit nearby in class, who work in the same office, who share the same parking lot, who eat in the same cafeteria. Look around. Mating starts with meeting. (For more on modern ways to connect people, see Close-up: Online Matchmaking and Speed Dating.)

Proximity breeds liking partly because of the **mere exposure effect**. Repeated exposure to novel stimuli increases our liking for them. This applies to nonsense syllables, musical selections, geometric figures, Chinese characters, human faces, and the letters of our own name (Moreland & Zajonc, 1982; Nuttin, 1987; Zajonc, 2001). We are even somewhat more likely to marry someone whose first or last name resembles our own (Jones et al., 2004).

So, within certain limits, familiarity breeds fondness (Bornstein, 1989, 1999). Researchers demonstrated this by having four equally attractive women silently attend a

Familiarity breeds acceptance

When this rare white penguin was born in the Sydney, Australia, zoo, his tuxedoed peers ostracized him. Zookeepers thought they would need to dye him black to gain acceptance. But after three weeks of contact, the other penguins came to accept him.

Close-up

Online Matchmaking and Speed Dating

Those who have not found a romantic partner in their immediate proximity may cast a wider net by joining the estimated 30 million people who each year try one of the some 1500 online dating services (Ellin, 2009). Online matchmaking works mostly by expanding the pool of potential mates (Finkel et al., 2012a,b).

Although published research on the effectiveness of Internet matchmaking services is sparse, this much seems well established: Some people, including occasional predators, dishonestly represent their age, attractiveness, occupation, or other details, and thus are not who they seem to be. Nevertheless, Katelyn McKenna and John Bargh and their colleagues have offered a surprising finding: Compared with relationships formed in person, Internet-formed friendships and romantic relationships have been, on average, more likely to last beyond two years (Bargh et al. 2002, 2004; McKenna & Bargh, 1998, 2000; McKenna et al., 2002). In one of their studies, people disclosed more, with less posturing, to those whom they met online. When conversing online with someone for 20 minutes, they felt more liking for that person than they did for someone they had met and talked with face to face. This was true even when (unknown to them) it was the same person! Internet friendships often feel as real and important to people as in-person relationships. That helps explain why one-third of American marriages occur among partners who met online, and why those marriages are slightly more stable and satisfying than marriages that began offline (Cacioppo et al., 2013).

Speed dating pushes the search for romance into high gear. In a process pioneered by a matchmaking Jewish rabbi,

© Dave Coverly

people meet a succession of prospective partners, either in person or via webcam (Bower, 2009). After a 3- to 8-minute conversation, people move on to the next person. (In an in-person meeting, one partner—usually the woman—remains seated and the other circulates.) Those who want to meet again can arrange for future contacts. For many participants, 4 minutes is enough time to form a feeling about a conversational partner and to register whether the partner likes them (Eastwick & Finkel, 2008a,b).

Researchers have quickly realized that speed dating offers a unique opportunity for studying influences on our first impressions of potential romantic partners. Among recent findings are these:

- Men are more transparent. Observers (male or female) watching videos of speed-dating encounters can read a man's level of romantic interest more accurately than a woman's (Place et al., 2009).
- Given more options, people's choices become more superficial. Meeting lots of potential partners leads people to focus on more easily assessed characteristics, such as height and weight (Lenton & Francesconi, 2010). This was true even when researchers controlled for time spent with each partner.
- Men wish for future contact with more of their speed dates; women tend to be more choosy. But this gender difference disappears if the conventional roles are reversed, so that men stay seated while women circulate (Finkel & Eastwick, 2009).

200-student class for zero, 5, 10, or 15 class sessions (Moreland & Beach, 1992). At the end of the course, students were shown slides of each woman and asked to rate her attractiveness. The most attractive? The ones they'd seen most often. The phenomenon would come as no surprise to the young Taiwanese man who wrote more than 700 letters to his girlfriend, urging her to marry him. She did marry—the mail carrier (Steinberg, 1993).

No face is more familiar than your own. And that helps explain an interesting finding by Lisa DeBruine (2004): We like other people when their faces incorporate some morphed features of our own. When DeBruine (2002) had

Ben Pruchnie/Getty Images

The mere exposure effect

The mere exposure effect applies even to ourselves. Because the human face is not perfectly symmetrical, the face we see in the mirror is not the same face our friends see. Most of us prefer the familiar mirror image, while our friends like the reverse (Mita et al., 1977). The Maggie Smith (actor) known to her fans is at left. The person she sees in the mirror each morning is shown at right, and that's the photo she would probably prefer.

AP Photo/Herman Miller

Beauty grows with mere exposure Herman Miller, Inc.'s famed Aeron chair initially received high comfort ratings but abysmal beauty ratings. To some it looked like “lawn furniture” or “a giant prehistoric insect” (Gladwell, 2005). But then, with design awards, media visibility, and imitators, the ugly duckling came to be the company's best-selling chair ever and to be seen as beautiful. With people, too, beauty lies partly in the beholder's eye and can grow with exposure.

“Personal beauty is a greater recommendation than any letter of introduction.” -ARISTOTLE, *APOTHEGEMS*, 330 B.C.E.

FYI

Percentage of Men and Women Who “Constantly Think About Their Looks”

	Men	Women
Canada	18%	20%
United States	17	27
Mexico	40	45
Venezuela	47	65

From Roper Starch survey, reported by McCool (1999).

McMaster University students (both men and women) play a game with a supposed other player, they were more trusting and cooperative when the other person's image had some of their own facial features morphed into it. In me I trust.

For our ancestors, the mere exposure effect had survival value. What was familiar was generally safe and approachable. What was unfamiliar was more often dangerous and threatening. Evolution may therefore have hard-wired into us the tendency to bond with those who are familiar and to be wary of those who are unfamiliar (Zajonc, 1998). If so, gut-level prejudice against those who are culturally different could be a primitive, automatic emotional response (Devine, 1995). It's what we do with our knee-jerk prejudice that matters, say researchers. Do we let those feelings control our behavior? Or do we monitor our feelings and act in ways that reflect our conscious valuing of human equality?

Physical Attractiveness

Once proximity affords us contact, what most affects our first impressions? The person's sincerity? Intelligence? Personality? Hundreds of experiments reveal that it is something far more superficial: physical appearance. This finding is unnerving for most of us who were taught that “beauty is only skin deep” and that “appearances can be deceiving.”

In one early study, researchers randomly matched new University of Minnesota students for a Welcome Week dance (Walster et al., 1966). Before the dance, the researchers gave each student a battery of personality and aptitude tests, and they rated each student's level of physical attractiveness. On the night of the blind date, the couples danced and talked for more than two hours and then took a brief intermission to rate their dates. What determined whether they liked each other? Only one thing seemed to matter: appearance. Both the men and the women liked good-looking dates best. Women are more likely than men to say that another's looks don't affect them (Lippa, 2007). But studies show that a man's looks do affect women's behavior (Feingold, 1990; Sprecher, 1989; Woll, 1986). Speed-dating experiments confirm that attractiveness influences first impressions for both sexes (Belot & Francesconi, 2006; Finkel & Eastwick, 2008).

Physical attractiveness also predicts how often people date and how popular they feel. It affects initial impressions of people's personalities. We don't assume that attractive people are more compassionate, but we do perceive them as healthier, happier, more sensitive, more successful, and more socially skilled (Eagly et al., 1991; Feingold, 1992; Hatfield & Sprecher, 1986). Attractive, well-dressed people are more likely to make a favorable impression on potential employers, and they tend to be more successful in their jobs (Cash & Janda, 1984; Langlois et al., 2000; Solomon, 1987). Income analyses show a penalty for plainness or obesity and a premium for beauty (Engemann & Owyang, 2005).

An analysis of 100 top-grossing films since 1940 found that attractive characters were portrayed as morally superior to unattractive characters (Smith et al., 1999). But Hollywood modeling doesn't explain why, to judge from their gazing times, even babies prefer attractive over unattractive faces (Langlois et al., 1987). So do some blind people, as University of Birmingham professor John Hull (1990, p. 23) discovered after going blind. A colleague's remarks on a woman's beauty would strangely affect his feelings. He found this “deplorable. . . . What can it matter to me what sighted men think of women . . . yet I do care what sighted men think, and I do not seem able to throw off this prejudice.”

For those who find importance of looks unfair and unenlightened, two attractiveness findings may be reassuring. First, people's attractiveness is surprisingly unrelated to their self-esteem and happiness (Diener et al., 1995; Major et al., 1984). Unless we have just compared ourselves with superattractive people, few of us (thanks, perhaps, to the mere exposure effect) view ourselves as unattractive (Thornton & Moore, 1993). Second, strikingly attractive people are sometimes suspicious that praise for their work may simply be a reaction to their looks. Less attractive people are more likely to accept praise as sincere (Berscheid, 1981).

In the eye of the beholder

Conceptions of attractiveness vary by culture. Yet some adult physical features, such as a youthful form and face, seem attractive everywhere.

Beauty is in the eye of the culture. Hoping to look attractive, people across the globe have pierced their noses, lengthened their necks, bound their feet, and dyed or painted their skin and hair. They have gorged themselves to achieve a full figure or liposuctioned fat to achieve a slim one, applied chemicals hoping to rid themselves of unwanted hair or to regrow wanted hair, strapped on leather garments to make their breasts seem smaller or surgically filled their breasts with silicone and put on Wonderbras to make them look bigger. Cultural ideals also change over time. For women in North America, the ultra-thin ideal of the Roaring Twenties gave way to the soft, voluptuous Marilyn Monroe ideal of the 1950s, only to be replaced by today's lean yet busty ideal.

If we're not born attractive, we may try to buy beauty. Americans now spend more on beauty supplies than on education and social services combined. Still not satisfied, millions undergo plastic surgery, teeth capping and whitening, Botox skin smoothing, and laser hair removal (ASPS, 2010).

Some aspects of attractiveness, however, do cross place and time (Cunningham et al., 2005; Langlois et al., 2000). By providing reproductive clues, bodies influence sexual attraction. As evolutionary psychologists explain (Module 15), men in many cultures, from Australia to Zambia, judge women as more attractive if they have a youthful, fertile appearance, suggested by a low waist-to-hip ratio (Karremans et al., 2010; Perilloux et al., 2010; Platek & Singh, 2010). Women feel attracted to healthy-looking men, but especially—and the more so when ovulating—to those who seem mature, dominant, masculine, and affluent (Gallup & Frederick, 2010; Gangestad et al., 2010). But faces matter, too. When people separately rate opposite-sex faces and bodies, the face tends to be the better predictor of overall physical attractiveness (Currie & Little, 2009; Peters et al., 2007).

People everywhere also seem to prefer physical features—noses, legs, physiques—that are neither unusually large nor small. An averaged face is attractive (**FIGURE 79.1**). In one clever demonstration, researchers digitized the faces of up to 32 college students and used a computer to average them (Langlois & Roggman, 1990). Students

Extreme makeover Greater wealth and concerns about appearance in China have led to increasing numbers of women seeking to alter their appearance. This woman underwent six months of grueling plastic surgery to transform her eyes, nose, chin, breasts, abdomen, bottom, legs, and skin in hopes of obtaining a career in film.

Photo/Teve/EyePress/Newscom

judged the averaged, composite faces as more attractive than 96 percent of the individual faces. One reason is that averaged faces are symmetrical, and people with symmetrical faces and bodies are more sexually attractive (Rhodes et al., 1999; Singh, 1995; Thornhill & Gangestad, 1994). Merge either half of your face with its mirror image and your symmetrical new face would boost your attractiveness a notch.

Our feelings also influence our attractiveness judgments. Imagine two people. The first is honest, humorous, and polite. The second is rude, unfair, and abusive. Which one is more attractive? Most people perceive the person with the appealing traits as also more physically attractive (Lewandowski et al., 2007). Those we like we find attractive. In a Rodgers and Hammerstein musical, Prince Charming asks Cinderella, “Do I love you because you’re beautiful, or are you beautiful because I love you?” Chances are it’s both. As we see our loved ones again and again, their physical imperfections grow less noticeable and their attractiveness grows more apparent (Beaman & Klentz, 1983; Gross & Crofton, 1977). Shakespeare said it in *A Midsummer Night’s Dream*: “Love looks not with the eyes, but with the mind.” Come to love someone and watch beauty grow.

Similarity

So proximity has brought you into contact with someone, and your appearance has made an acceptable first impression. What now influences whether you will become friends? As you get to know each other better, will the chemistry be better if you are opposites or if you are alike?

It makes a good story—extremely different types living in harmonious union: Rat, Mole, and Badger in *The Wind in the Willows*, Frog and Toad in Arnold Lobel’s books. The stories delight us by expressing what we seldom experience, for in real life, opposites *retract* (Rosenbaum, 1986). Compared with randomly paired people, friends and couples are far more likely to share common attitudes, beliefs, and interests (and, for that matter, age, religion, race, education, intelligence, smoking behavior, and economic status).

Moreover, the more alike people are, the more their liking endures (Byrne, 1971). Journalist Walter Lippmann was right to suppose that love lasts “when the lovers love many things together, and not merely each other.” Similarity breeds content. Dissimilarity often fosters disfavor, which helps explain many straight men’s disapproval of gay men who are doubly dissimilar from themselves in sexual orientation and gender roles (Lehavot & Lambert, 2007).

Proximity, attractiveness, and similarity are not the only determinants of attraction. We also like those who like us. This is especially so when our self-image is low. When we believe someone likes us, we feel good and respond to them warmly, which leads them to like us even more (Curtis & Miller, 1986). To be liked is powerfully rewarding.

Indeed, all the findings we have considered so far can be explained by a simple *reward theory of attraction*: We will like those whose behavior is rewarding to us, and we will continue relationships that offer more rewards than costs. When people live or work in close proximity with us, it costs less time and effort to develop the friendship and enjoy its benefits. When people are attractive, they are aesthetically pleasing, and associating with them can be socially rewarding. When people share our views, they reward us by validating our own.

Romantic Love

79-2 How does romantic love typically change as time passes?

Sometimes people move quickly from initial impressions, to friendship, to the more intense, complex, and mysterious state of romantic love. If love endures, temporary passionate love will mellow into a lingering companionate love (Hatfield, 1988).

Passionate Love

A key ingredient of **passionate love** is arousal. The two-factor theory of emotion (Module 41) can help us understand this intense positive absorption in another (Hatfield, 1988). That theory assumes that:

- Emotions have two ingredients—*physical arousal* plus *cognitive appraisal*.
- Arousal from any source can enhance one emotion or another, depending on how we interpret and label the arousal.

In tests of the two-factor theory, college men have been aroused by fright, by running in place, by viewing erotic materials, or by listening to humorous or repulsive monologues. They were then introduced to an attractive woman and asked to rate her (or their girlfriend). Unlike unaroused men, the stirred-up men attributed some of their arousal to the woman or girlfriend, and felt more attracted to her (Carducci et al., 1978; Dermer & Pyszczynski, 1978; White & Kight, 1984).

A sample experiment: Researchers studied people crossing two bridges above British Columbia's rocky Capilano River (Dutton & Aron, 1974, 1989). One, a swaying footbridge, was 230 feet above the rocks; the other was low and solid. The researchers had an attractive young woman intercept men coming off each bridge, and ask their help in filling out a short questionnaire. She then offered her phone number in case they wanted to hear more about her project. Far more of those who had just crossed the high bridge—which left their hearts pounding—accepted the number and later called the woman. To be revved up and to associate some of that arousal with a desirable person is to feel the pull of passion. Adrenaline makes the heart grow fonder. And when sexual desire is supplemented by a growing attachment, the result is the passion of romantic love (Berscheid, 2010).

Companionate Love

Although the desire and attachment of romantic love often endure, the intense absorption in the other, the thrill of the romance, the giddy “floating on a cloud” feelings typically fade. Does this mean the French are correct in saying that “love makes the time pass and time makes love pass”? Or can friendship and commitment keep a relationship going after the passion cools?

The evidence indicates that, as love matures, it becomes a steadier **companionate love**—a deep, affectionate attachment (Hatfield, 1988). The flood of passion-facilitating hormones (testosterone, dopamine, adrenaline) subsides and another hormone, oxytocin, supports feelings of trust, calmness, and bonding with the mate. In the most satisfying of marriages, attraction and sexual desire endure, minus the obsession of early stage romance (Acevedo & Aron, 2009).

There may be adaptive wisdom to the shift from passion to attachment (Reis & Aron, 2008). Passionate love often produces children, whose survival is aided by the parents' waning obsession with each other. Failure to appreciate passionate love's limited half-life can doom a relationship (Berscheid et al., 1984). Indeed, recognizing the short duration of obsessive passionate love, some societies deem such feelings to be an irrational reason for marrying. Better, they say, to choose (or have someone choose for you) a partner with a compatible background and interests. Non-Western cultures, where people rate love less important for marriage, do have lower divorce rates (Levine et al., 1995).

FYI

Note the difference between lust (immediate desire) and romantic love (desire + attachment).

passionate love an aroused state of intense positive absorption in another, usually present at the beginning of a love relationship.

companionate love the deep affectionate attachment we feel for those with whom our lives are intertwined.

“When two people are under the influence of the most violent, most insane, most delusive, and most transient of passions, they are required to swear that they will remain in that excited, abnormal, and exhausting condition continuously until death do them part.” —GEORGE BERNARD SHAW, “GETTING MARRIED,” 1908

HI & LOIS

One key to a gratifying and enduring relationship is **equity**. When equity exists—when both partners receive in proportion to what they give—their chances for sustained and satisfying companionate love are good (Gray-Little & Burks, 1983; VanYperen & Buunk, 1990). In one national survey, “sharing household chores” ranked third, after “faithfulness” and a “happy sexual relationship,” on a list of nine things people associated with successful marriages. “I like hugs. I like kisses. But what I really love is help with the dishes,” summarized the Pew Research Center (2007).

Equity’s importance extends beyond marriage. Mutually sharing self and possessions, making decisions together, giving and getting emotional support, promoting and caring about each other’s welfare—all of these acts are at the core of every type of loving relationship (Sternberg & Grajek, 1984). It’s true for lovers, for parent and child, and for intimate friends.

Another vital ingredient of loving relationships is **self-disclosure**, the revealing of intimate details about ourselves—our likes and dislikes, our dreams and worries, our proud and shameful moments. “When I am with my friend,” noted the Roman statesman Seneca, “me thinks I am alone, and as much at liberty to speak anything as to think it.” Self-disclosure breeds liking, and liking breeds self-disclosure (Collins & Miller, 1994). As one person reveals a little, the other reciprocates, the first then reveals more, and on and on, as friends or lovers move to deeper and deeper intimacy (Baumeister & Bratslavsky, 1999).

One experiment marched student pairs through 45 minutes of increasingly self-disclosing conversation—from “When did you last sing to yourself?” to “When did you last cry in front of another person? By yourself?” Others spent the time with small-talk questions, such as “What was your high school like?” (Aron et al., 1997). By the experiment’s end, those experiencing the escalating intimacy felt remarkably close to their conversation partner, much closer than did the small-talkers.

Intimacy can also grow from pausing to ponder and write our feelings. In another study, researchers invited one person from each of 86 dating couples to spend 20 minutes a day over three days either writing their deepest thoughts and feelings about the relationship or writing merely about their daily activities (Slatcher & Pennebaker, 2006). Those who had written about their feelings expressed more emotion in their instant messages with their partners in the days following, and 77 percent were still dating three months later (compared with 52 percent of those who had written about their activities).

In addition to equity and self-disclosure, a third key to enduring love is *positive support*. While relationship conflicts are inevitable, we can ask ourselves whether our communications more often express sarcasm or support, scorn or sympathy, sneers or smiles. For unhappy couples,

equity a condition in which people receive from a relationship in proportion to what they give to it.

self-disclosure revealing intimate aspects of oneself to others.

Love is an ancient thing In 2007, a 5000- to 6000-year-old “Romeo and Juliet” young couple was unearthed locked in embrace, near Rome.

AP Photo/Archaeological Society SAP, Inc

disagreements, criticisms, and put downs are routine. For happy couples in enduring relationships, positive interactions (compliments, touches, laughing) outnumber negative interactions (sarcasm, disapproval, insults) by at least 5 to 1 (Gottman, 2007; see also Sullivan et al., 2010).

In the mathematics of love, self-disclosing intimacy + mutually supportive equity = enduring companionate love.

Before You Move On

▶ ASK YOURSELF

When you think of some of the older couples you know, which ones seem to experience companionate love? How do you think they've achieved it?

▶ TEST YOURSELF

How does being physically attractive influence others' perceptions?

Answers to the Test Yourself questions can be found in Appendix E at the end of the book.

Module 79 Review

79-1

Why do we befriend or fall in love with some people but not others?

- Proximity (geographical nearness) increases liking, in part because of the *mere exposure effect*—exposure to novel stimuli increases liking of those stimuli.
- Physical attractiveness increases social opportunities and improves the way we are perceived.
- Similarity of attitudes and interests greatly increases liking, especially as relationships develop. We also like those who like us.

79-2

How does romantic love typically change as time passes?

- Intimate love relationships start with *passionate love*—an intensely aroused state.
- Over time, the strong affection of *companionate love* may develop, especially if enhanced by an *equitable* relationship and by intimate *self-disclosure*.

Multiple-Choice Questions

1. Which of the following terms describes our geographic nearness to another person?
 - a. Mere exposure effect
 - b. Proximity
 - c. Similarity
 - d. Ingroup bias
 - e. Symmetry
2. Which of the following is an example of the mere exposure effect?
 - a. Adrianna has started arriving tardy to her second period class to avoid a group of kids in the hall who constantly tease her.
 - b. Abe has biked the same route to school so many times that he no longer has to think about where to turn.
 - c. Daiyu has seen the same toothpaste ad on television a hundred times. Each time she sees it she hates it more.
 - d. Abdul has always loved dogs, so he adopted one from the local shelter.
 - e. Guiren didn't like sushi the first couple times he tried it, but his friend encouraged him to keep eating it and now it's one of his favorite foods.
3. Which of the following is an aspect of physical attractiveness that appears to be true across cultures?
 - a. Indications of reproductive health
 - b. Height
 - c. Weight
 - d. Size of the ears
 - e. Shape of the chin
4. Over time, which of the following is typically true of the relationship between passionate love and companionate love?
 - a. Passionate and companionate love both decrease.
 - b. Passionate love increases and companionate love decreases.
 - c. Passionate and companionate love both increase.
 - d. Passionate love decreases and companionate love increases.
 - e. There is no consistent relationship between the levels of passionate love and companionate love.

Practice FRQs

1. List the three major factors that influence attraction.

Answer

1 point: Proximity, which is geographic nearness.

1 point: Physical attractiveness.

1 point: Similarity.

2. Describe one key factor present in passionate love and two key factors present in companionate love.

(3 points)

Module 80

Altruism, Conflict, and Peacemaking

Module Learning Objectives

- 80-1** Identify the times when people are most—and least—likely to help.
- 80-2** Discuss how social exchange theory and social norms explain helping behavior.
- 80-3** Explain how social traps and mirror-image perceptions fuel social conflict.
- 80-4** Discuss how we can transform feelings of prejudice, aggression, and conflict into attitudes that promote peace.

Altruism

- 80-1** When are people most—and least—likely to help?

Altruism is an unselfish concern for the welfare of others. In rescuing his jailer, Dirk Willems exemplified altruism (Unit XIV opener). So also did Carl Wilkens and Paul Rusesabagina in Kigali, Rwanda. Wilkens, a Seventh Day Adventist missionary, was living there in 1994 with his family when Hutu militia began to slaughter the Tutsi. The U.S. government, church leaders, and friends all implored Wilkens to leave. He refused. After evacuating his family, and even after every other American had left Kigali, he alone stayed and contested the 800,000-person genocide. When the militia came to kill him and his Tutsi servants, Wilkens' Hutu neighbors deterred them. Despite repeated death threats, he spent his days running roadblocks to take food and water to orphanages and to negotiate, plead, and bully his way through the bloodshed, saving lives time and again. "It just seemed the right thing to do," he later explained (Kristof, 2004).

Elsewhere in Kigali, Rusesabagina, a Hutu married to a Tutsi and the acting manager of a luxury hotel, was sheltering more than 1200 terrified Tutsis and moderate Hutus. When international peacekeepers abandoned the city and hostile militia threatened his guests in the "Hotel Rwanda" (as it came to be called in a 2004 movie), the courageous Rusesabagina began cashing in past favors. He bribed the militia and telephoned influential people abroad to exert pressure on local authorities, thereby sparing the lives of the hotel's occupants from the surrounding chaos.

Both Wilkens and Rusesabagina were displaying altruism. Altruism became a major concern of social psychologists after an especially vile act of sexual violence. On March 13, 1964, a stalker repeatedly stabbed Kitty Genovese, then raped her as she lay dying outside her Queens, New York, apartment at 3:30 A.M. "Oh, my God, he stabbed me!"

altruism unselfish regard for the welfare of others.

"Probably no single incident has caused social psychologists to pay as much attention to an aspect of social behavior as Kitty Genovese's murder." -R. LANCE SHOTLAND (1984)

Genovese screamed into the early morning stillness. “Please help me!” Windows opened and lights went on as neighbors (38 of them, said an initial *New York Times* report, though that number was later contested) heard her screams. Her attacker fled and then returned to stab and rape her again. Not until he had fled for good did anyone so much as call the police, at 3:50 A.M.

Bystander Intervention

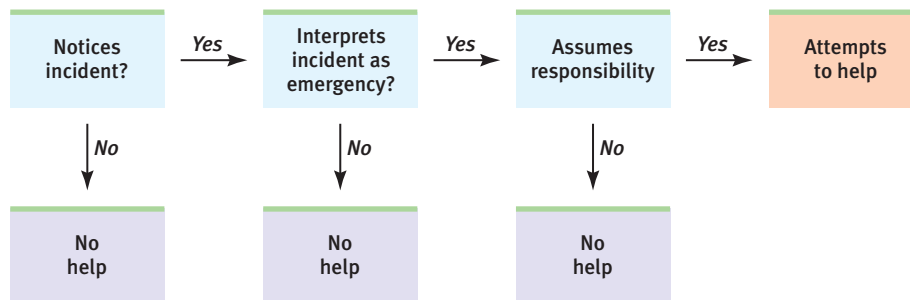

Reflecting on initial reports of the Genovese murder and other such tragedies, most commentators were outraged by the bystanders’ “apathy” and “indifference.” Rather than blaming the onlookers, social psychologists John Darley and Bibb Latané (1968b) attributed their inaction to an important situational factor—the presence of others. Given certain circumstances, they suspected, most of us might behave similarly.

After staging emergencies under various conditions, Darley and Latané assembled their findings into a decision scheme: We will help only if the situation enables us first to *notice* the incident, then to *interpret* it as an emergency, and finally to *assume responsibility* for helping (FIGURE 80.1). At each step, the presence of others can turn us away from the path that leads to helping.

Figure 80.1

The decision-making process for bystander intervention

Before helping, one must first notice an emergency, then correctly interpret it, and then feel responsible. (From Darley & Latané, 1968b.)

Darley and Latané reached their conclusions after interpreting the results of a series of experiments. For example, they simulated a physical emergency in their laboratory as students participated in a discussion over an intercom. Each student was in a separate cubicle, and only the person whose microphone was switched on could be heard. When his turn came, one student (an accomplice of the experimenters) made sounds as though he were having an epileptic seizure, and he called for help (Darley & Latané, 1968a).

How did the other students react? As FIGURE 80.2 shows, those who believed only they could hear the victim—and therefore thought they alone were responsible for helping him—usually went to his aid. Students who thought others also could hear the victim’s cries were more likely to ignore the victim. When more people shared responsibility for helping—when there was a *diffusion of responsibility*—any single listener was less likely to help.

Hundreds of additional experiments have confirmed this **bystander effect**. For example, researchers and their assistants took 1497 elevator rides in three cities and “accidentally” dropped coins or pencils in front of 4813 fellow passengers (Latané & Dabbs, 1975). When alone with the person in need, 40 percent helped; in the presence of 5 other bystanders, only 20 percent helped.

Observations of behavior in thousands of such situations—relaying an emergency phone call, aiding a stranded motorist, donating blood, picking up dropped books, contributing money, giving time—show that the *best* odds of our helping someone occur when

- the person appears to need and deserve help.
- the person is in some way similar to us.
- the person is a woman.

bystander effect the tendency for any given bystander to be less likely to give aid if other bystanders are present.

AP® Exam Tip

Common sense suggests that you would be more likely to get help if there are more people around, but research on the bystander effect has in fact shown just the opposite is true. This concept often shows up on the AP® exam, so be sure you understand it.

- we have just observed someone else being helpful.
- we are not in a hurry.
- we are in a small town or rural area.
- we are feeling guilty.
- we are focused on others and not preoccupied.
- we are in a good mood.

This last result, that happy people are helpful people, is one of the most consistent findings in all of psychology. As poet Robert Browning (1868) observed, “Oh, make us happy and you make us good!” It doesn’t matter how we are cheered. Whether by being made to feel successful and intelligent, by thinking happy thoughts, by finding money, or even by receiving a posthypnotic suggestion, we become more generous and more eager to help (Carlson et al., 1988). And given a feeling of elevation after witnessing or learning of someone else’s self-giving deed, our helping will become even more pronounced (Schnall et al., 2010).

So happiness breeds helpfulness. But it’s also true that helpfulness breeds happiness. Making charitable donations activates brain areas associated with reward (Harbaugh et al., 2007). That helps explain a curious finding: People who give money away are happier than those who spend it almost entirely on themselves. In one experiment, researchers gave people an envelope with cash and instructions either to spend it on themselves or to spend it on others (Dunn et al., 2008). Which group was happiest at the day’s end? It was, indeed, those assigned to the spend-it-on-others condition.

The Norms for Helping

80-2 How do social exchange theory and social norms explain helping behavior?

Why do we help? One widely held view is that self-interest underlies all human interactions, that our constant goal is to maximize rewards and minimize costs. Accountants call it *cost-benefit analysis*. Philosophers call it *utilitarianism*. Social psychologists call it **social exchange theory**. If you are pondering whether to donate blood, you may weigh the costs of doing so (time, discomfort, and anxiety) against the benefits (reduced guilt, social approval, and good feelings). If the rewards exceed the costs, you will help.

Others believe that we help because we have been socialized to do so, through norms that prescribe how we *ought* to behave. Through socialization, we learn the **reciprocity norm**, the expectation that we should return help, not harm, to those who have helped us. In our relations with others of similar status, the reciprocity norm compels us to give (in favors, gifts, or social invitations) about as much as we receive.

The reciprocity norm kicked in after Dave Tally, a Tempe, Arizona, homeless man, found \$3300 in a backpack that had been lost by an Arizona State University student headed to buy a used car (Lacey, 2010). Instead of using the cash for much-needed bike repairs, food, and shelter, Tally turned the backpack in to the social service agency where he volunteered. To reciprocate Tally’s help, the student thanked him with a reward. Hearing about Tally’s self-giving deeds, dozens of others also sent him money and job offers.

Figure 80.2
Responses to a simulated physical emergency When people thought they alone heard the calls for help from a person they believed to be having an epileptic seizure, they usually helped. But when they thought four others were also hearing the calls, fewer than one-third responded. (From Darley & Latané, 1968a.)

social exchange theory

the theory that our social behavior is an exchange process, the aim of which is to maximize benefits and minimize costs.

reciprocity norm an expectation that people will help, not hurt, those who have helped them.

Subway hero Wesley Autrey

"I don't feel like I did something spectacular; I just saw someone who needed help."

We also learn a **social-responsibility norm**: that we should help those who need our help—young children and others who cannot give as much as they receive—even if the costs outweigh the benefits. Construction worker Wesley Autrey exemplified the social-responsibility norm on January 2, 2007. He and his 6- and 4-year-old daughters were awaiting a New York City subway train when, before them, a man collapsed in a seizure, got up, then stumbled to the platform's edge and fell onto the tracks. With train headlights approaching, "I had to make a split decision," Autrey later recalled (Buckley, 2007). His decision, as his girls looked on in horror, was to leap from the platform, push the man off the tracks and into a foot-deep space between them, and lay atop him. As the train screeched to a halt, five cars traveled just above his head, leaving grease on his knit cap. When Autrey cried out, "I've got two daughters up there. Let them know their father is okay," the onlookers erupted into applause.

People who attend weekly religious services often are admonished to practice the social-responsibility norm, and sometimes they do. In American surveys, they have reported twice as many volunteer hours spent helping the poor and infirm, compared with those who rarely or never attend religious services (Hodgkinson & Weitzman, 1992; Independent Sector, 2002). Between 2006 and 2008, Gallup polls sampled more than 300,000 people across 140 countries, comparing those "highly religious" (who said religion was important to them and who had attended a religious service in the prior week) with those less religious. The highly religious, despite being poorer, were about 50 percent more likely to report having "donated money to a charity in the last month" and to have volunteered time to an organization (Pelham & Crabtree, 2008). Although positive social norms encourage generosity and enable group living, conflicts often divide us.

Conflict and Peacemaking

We live in surprising times. With astonishing speed, recent democratic movements swept away totalitarian rule in Eastern European and Arab countries, and hopes for a new world order displaced the Cold War chill. And yet, the twenty-first century began with terrorist acts and war. *Every day*, the world has continued to spend more than \$3 billion for arms and armies—money that could have been used for housing, nutrition, education, and health care. Knowing that wars begin in human minds, psychologists have wondered: What in the human mind causes destructive conflict? How might the perceived threats of social diversity be replaced by a spirit of cooperation?

Elements of Conflict

80-3

How do social traps and mirror-image perceptions fuel social conflict?

To a social psychologist, a **conflict** is a perceived incompatibility of actions, goals, or ideas. The elements of conflict are much the same, whether we are speaking of nations at war, cultural groups feuding within a society, or partners sparring in a relationship. In each situation, people become enmeshed in potentially destructive processes that can produce results no one wants. Among these processes are social traps and distorted perceptions.

SOCIAL TRAPS

In some situations, we support our collective well-being by pursuing our personal interests. As capitalist Adam Smith wrote in *The Wealth of Nations* (1776), "It is not from the benevolence of the butcher, the brewer, or the baker that we expect our dinner, but from their regard to their own interest." In other situations, we harm our collective well-being by pursuing our personal interests. Such situations are **social traps**.

social-responsibility norm

an expectation that people will help those needing their help.

conflict a perceived incompatibility of actions, goals, or ideas.

social trap a situation in which the conflicting parties, by each rationally pursuing their self-interest rather than the good of the group, become caught in mutually destructive behavior.

		Person 1	
		Choose A	Choose B
Person 2	Choose A	Optimal outcome +\$5	+\$10
	Choose B	+\$5	-\$5
		Choose A	Choose B
Person 2	Choose A	-\$5	Probable outcome 0
	Choose B	+\$10	0

Figure 80.3

Social-trap game matrix By pursuing our self-interest and not trusting others, we can end up losers. To illustrate this, imagine playing the game on the left. The light-orange triangles show the outcomes for Person 1, which depend on the choices made by both players. If you were Person 1, would you choose A or B? (This game is called a *non-zero-sum* game because the outcomes need not add up to zero; both sides can win or both can lose.)

Consider the simple game matrix in **FIGURE 80.3**, which is similar to those used in experiments with countless thousands of people. Both sides can win or both can lose, depending on the players' individual choices. Pretend you are Person 1, and that you and Person 2 will each receive the amount shown after you separately choose either A or B. (You might invite someone to look at the matrix with you and take the role of Person 2.) Which do you choose—A or B?

You and Person 2 are caught in a dilemma. If you both choose A, you both benefit, making \$5 each. Neither of you benefits if you both choose B, for neither of you makes anything. Nevertheless, on any single trial you serve your own interests if you choose B: You can't lose, and you might make \$10. But the same is true for the other person. Hence, the social trap: As long as you both pursue your own immediate best interest and choose B, you will both end up with nothing—the typical result—when you could have made \$5.

Many real-life situations similarly pit our individual interests against our communal well-being. Individual whalers reasoned that the few whales they took would not threaten the species and that if they didn't take them others would anyway. The result: Some species of whales became endangered. Ditto for the buffalo hunters of yesterday and the elephant-tusk poachers of today. Individual car owners and home owners reason, "It would cost me comfort or money to buy a more fuel-efficient car and furnace. Besides, the fossil fuels I burn don't noticeably add to the greenhouse gases." When enough others reason similarly, the collective result threatens disaster—climate change, rising seas, and more extreme weather.

AP Photo/Lisa Poole

Not in my ocean! Many people support alternative energy sources, including wind turbines. But proposals to construct wind farms in real-world neighborhoods elicit less support. One such proposal, for locating wind turbines off the coast of Massachusetts' Nantucket Island, produced heated debate over the future benefits of clean energy versus the costs of altering treasured ocean views and, possibly, migratory bird routes.

Social traps challenge us to find ways of reconciling our right to pursue our personal well-being with our responsibility for the well-being of all. Psychologists have therefore explored ways to convince people to cooperate for their mutual betterment—through agreed-upon *regulations*, through better *communication*, and through promoting *awareness* of our responsibilities toward community, nation, and the whole of humanity (Dawes, 1980; Linder, 1982; Sato, 1987). Given effective regulations, communication, and awareness, people more often cooperate, whether it be in playing a laboratory game or the real game of life.

ENEMY PERCEPTIONS

Psychologists have noted that those in conflict have a curious tendency to form diabolical images of one another. These distorted images are, ironically, so similar that we call them **mirror-image perceptions**: As we see “them”—as untrustworthy, with evil intentions—so “they” see us. Each demonizes the other.

Mirror-image perceptions can often feed a vicious cycle of hostility. If Juan believes Maria is annoyed with him, he may snub her, causing her to act in ways that justify his perception. As with individuals, so with countries. Perceptions can become **self-fulfilling prophecies**. They may confirm themselves by influencing the other country to react in ways that seem to justify them.

Participants tend to see their own actions as responses to provocation, not as the causes of what happens next. Perceiving themselves as returning tit for tat, they often hit back harder, as University College London volunteers did in one experiment (Shergill et al., 2003). Their task: After feeling pressure on their own finger, they were to use a mechanical device to press on another volunteer’s finger. Although told to reciprocate with the same amount of pressure, they typically responded with about 40 percent more force than they had just experienced. Despite seeking only to respond in kind, their touches soon escalated to hard presses, much as when each child after a fight claims that “I just poked him, but he hit me harder.”

Perceived provocations feed similar cycles of hostility on the world stage. In 2001, newly elected U.S. President George W. Bush spoke of Saddam Hussein: “Some of today’s tyrants are gripped by an implacable hatred of the United States of America. They hate our friends, they hate our values, they hate democracy and freedom and individual liberty. Many care little for the lives of their own people.” Hussein reciprocated the perception in 2002. The United States, he said, is “an evil tyrant,” with Satan as its protector. It lusts for oil and aggressively attacks those who “defend what is right.”

The point is not that truth must lie midway between two such views (one may be more accurate). The point is that enemy perceptions often form mirror images. Moreover, as enemies change, so do perceptions. In American minds and media, the “bloodthirsty, cruel, treacherous” Japanese of World War II later became our “intelligent, hardworking, self-disciplined, resourceful allies” (Gallup, 1972).

Promoting Peace

80-4

How can we transform feelings of prejudice, aggression, and conflict into attitudes that promote peace?

How can we make peace? Can contact, cooperation, communication, and conciliation transform the antagonisms fed by prejudice and conflicts into attitudes that promote peace? Research indicates that, in some cases, they can.

CONTACT

Does it help to put two conflicting parties into close contact? It depends. When contact is noncompetitive and between parties of equal status, such as fellow store clerks, it typically helps. Initially prejudiced co-workers of different races have, in such circumstances, usually

mirror-image perceptions

mutual views often held by conflicting people, as when each side sees itself as ethical and peaceful and views the other side as evil and aggressive.

self-fulfilling prophecy a belief that leads to its own fulfillment.

come to accept one another. This finding is confirmed by a statistical digest of more than 500 studies of face-to-face contact with outgroups (such as ethnic minorities, the elderly, and those with disabilities). Among the quarter-million people studied across 38 nations, contact has been correlated with, or in experimental studies has led to, more positive attitudes (Pettigrew & Tropp, 2011). Some examples:

- With interracial contact, South African Whites' and Blacks' "attitudes [have moved] into closer alignment" (Dixon et al, 2007; Finchilescu & Tredoux, 2010). In South Africa, as elsewhere, the contact effect is somewhat less for lower-status ethnic groups' views of higher-status groups (Durrheim & Dixon, 2010; Gibson & Claassen, 2010).
- Heterosexuals' attitudes toward gay people are influenced not only by what they know but also by whom they know (Smith et al., 2009). In surveys, the reason people most often give for becoming more supportive of same-sex marriage is "having friends, family or acquaintances who are gay or lesbian" (Pew, 2013).
- Friendly contact, say between Blacks and Whites, improves attitudes not only toward one another, but also toward other outgroups, such as Hispanics (Tausch et al., 2010).
- Even indirect contact with an outgroup member (via story reading or through a friend who has an outgroup friend) has reduced prejudice (Cameron & Rutland, 2006; Pettigrew et al., 2007).

However, contact is not always enough. In most desegregated schools, ethnic groups resegregate themselves in the lunchrooms and classrooms, and on the school grounds (Alexander & Tredoux, 2010; Clack et al., 2005; Schofield, 1986). People in each group often think that they would welcome more contact with the other group, but they assume the other group does not reciprocate the wish (Richeson & Shelton, 2007). "I don't reach out to them, because I don't want to be rebuffed; they don't reach out to me, because they're just not interested." When such mirror-image misperceptions are corrected, friendships may then form and prejudices melt.

COOPERATION

To see if enemies could overcome their differences, researcher Muzafer Sherif (1966) set a conflict in motion. He separated 22 Oklahoma City boys into two separate camp areas. Then he had the two groups compete for prizes in a series of activities. Before long, each group became intensely proud of itself and hostile to the other group's "sneaky," "smart-alecky stinkers." Food wars broke out. Cabins were ransacked. Fistfights had to be broken up by camp counselors. Brought together, the two groups avoided each other, except to taunt and threaten. Little did they know that within a few days, they would be friends.

Sherif accomplished this by giving them **superordinate goals**—shared goals that could be achieved only through cooperation. When he arranged for the camp water supply to "fail," all 22 boys had to work together to restore water. To rent a movie in those pre-DVD days, they all had to pool their resources. To move a stalled truck, the boys needed to combine their strength, pulling and pushing together. Having used isolation and competition to make strangers into enemies, Sherif used shared predicaments and goals to turn enemies into friends. What reduced conflict was not mere contact, but *cooperative* contact.

A shared predicament likewise had a powerfully unifying effect in the weeks after 9/11. Patriotism soared as Americans felt "we" were under attack. Gallup-surveyed approval of "our President" shot up from 51 percent the week before the attack to a highest-ever 90 percent level 10 days after (Newport, 2002). In chat groups and everyday speech, even the word *we* (relative to *I*) surged in the immediate aftermath (Pennebaker, 2002).

"You cannot shake hands with a clenched fist." -INDIRA GANDHI, 1971

superordinate goals shared goals that override differences among people and require their cooperation.

AFP/Getty Images

Striving for peace The road to reconciliation in the Middle East may be arduous, but as former U.N. Secretary-General Kofi Annan noted in his Nobel lecture, “Most of us have overlapping identities which unite us with very different groups. We *can* love what we are, without hating what—and who—we are *not*. We can thrive in our own tradition, even as we learn from others” (2001). Pictured here are Palestinian statesman Mahmoud Abbas, Israeli Prime Minister Benjamin Netanyahu, and U. S. President Barack Obama.

At such times, cooperation can lead people to define a new, inclusive group that dissolves their former subgroups (Dovidio & Gaertner, 1999). To accomplish this, you might seat members of two groups not on opposite sides, but alternately around a table. Give them a new, shared name. Have them work together. Then watch “us” and “them” become “we.” After 9/11, one 18-year-old New Jersey man described this shift in his own social identity: “I just thought of myself as Black. But now I feel like I’m an American, more than ever” (Sengupta, 2001). In a real experiment, White Americans who read a newspaper article about a terrorist threat against all Americans subsequently expressed reduced prejudice against Black Americans (Dovidio et al., 2004).

If cooperative contact between rival group members encourages positive attitudes, might this principle bring people together in multicultural schools? Could interracial friendships replace competitive classroom situations with cooperative ones? Could cooperative learning maintain or even enhance student achievement? Experiments with adolescents from 11 countries confirm that, in each case, the answer is *Yes* (Roseth et al., 2008). In the classroom as in the sports arena, members of interracial groups who work together on projects typically come to feel friendly toward one another. Knowing this, thousands of teachers have made interracial cooperative learning part of their classroom experience.

The power of cooperative activity to make friends of former enemies has led psychologists to urge increased international exchange and cooperation. As we engage in mutually beneficial trade, as we work to protect our common destiny on this fragile planet, and as we become more aware that our hopes and fears are shared, we can transform misperceptions that feed conflict into feelings of solidarity based on common interests.

COMMUNICATION

When real-life conflicts become intense, a third-party mediator—a marriage counselor, labor mediator, diplomat, community volunteer—may facilitate much-needed communication (Rubin et al., 1994). Mediators help each party to voice its viewpoint and to understand the other’s needs and goals. If successful, mediators can replace a competitive *win-lose* orientation with a cooperative *win-win* orientation that leads to a mutually beneficial resolution. A classic example: Two friends, after quarreling over an orange, agreed to

Superordinate goals override differences Cooperative efforts to achieve shared goals are an effective way to break down social barriers.

AP Photo/Grant Hindsley

split it. One squeezed his half for juice. The other used the peel from her half to flavor a cake. If only the two had understood each other's motives, they could have hit on the win-win solution of one having all the juice, the other all the peel.

CONCILIATION

Understanding and cooperative resolution are most needed, yet least likely, in times of anger or crisis (Bodenhausen et al., 1994; Tetlock, 1988). When conflicts intensify, images become more stereotyped, judgments more rigid, and communication more difficult, or even impossible. Each party is likely to threaten, coerce, or retaliate. In the weeks before the Persian Gulf war, the first President George Bush threatened, in the full glare of publicity, to “kick Saddam’s ass.” Saddam Hussein communicated in kind, threatening to make Americans “swim in their own blood.”

Under such conditions, is there an alternative to war or surrender? Social psychologist Charles Osgood (1962, 1980) advocated a strategy of *Graduated and Reciprocated Initiatives in Tension-Reduction*, nicknamed **GRIT**. In applying GRIT, one side first announces its recognition of mutual interests and its intent to reduce tensions. It then initiates one or more small, conciliatory acts. Without weakening one’s retaliatory capability, this modest beginning opens the door for reciprocity by the other party. Should the enemy respond with hostility, one reciprocates in kind. But so, too, with any conciliatory response.

In laboratory experiments, small conciliatory gestures—a smile, a touch, a word of apology—have allowed both parties to begin edging down the tension ladder to a safer rung where communication and mutual understanding can begin (Lindsfold et al., 1978, 1988). In a real-world international conflict, U.S. President John F. Kennedy’s gesture of stopping atmospheric nuclear tests began a series of reciprocated conciliatory acts that culminated in the 1963 atmospheric test-ban treaty.

As working toward shared goals reminds us, we are more alike than different. Civilization advances not by conflict and cultural isolation, but by tapping the knowledge, the skills, and the arts that are each culture’s legacy to the whole human race. Thanks to cultural sharing, every modern society is enriched by a cultural mix (Sowell, 1991). We have China to thank for paper and printing and for the magnetic compass that opened the great explorations. We have Egypt to thank for trigonometry. We have the Islamic world and India’s Hindus to thank for our Arabic numerals. While celebrating and claiming these diverse cultural legacies, we can also welcome the enrichment of today’s social diversity. We can view ourselves as instruments in a human orchestra. And we—this book’s worldwide readers—can therefore each affirm our own culture’s heritage while building bridges of communication, understanding, and cooperation across our cultural traditions.

“To begin with, I would like to express my sincere thanks and deep appreciation for the opportunity to meet with you. While there are still profound differences between us, I think the very fact of my presence here today is a major breakthrough.”

GRIT Graduated and Reciprocated Initiatives in Tension-Reduction—a strategy designed to decrease international tensions.

Before You Move On

▶ ASK YOURSELF

Do you regret not getting along with some friend or family member? How might you go about reconciling that relationship?

▶ TEST YOURSELF

Why didn’t anybody help Kitty Genovese? What social relations principle did this incident illustrate?

Answers to the Test Yourself questions can be found in Appendix E at the end of the book.

* * *

If you just finished reading this book, your introduction to psychological science is completed. Our tour of psychological science has taught me much—and you, too?—about our moods and memories, about the reach of our unconscious, about how we flourish and struggle, about how we perceive our physical and social worlds, and about how our biology and culture in turn shape us. My hope, as your guide on this tour, is that you have shared some of my fascination, grown in your understanding and compassion, and sharpened your critical thinking. I also hope you enjoyed the ride.

With every good wish in your future endeavors (including the AP® exam!),
David G. Myers
www.davidmyers.org

Module 80 Review

80-1

When are people most—and least—likely to help?

- *Altruism* is unselfish regard for the well-being of others.
- We are most likely to help when we (a) notice an incident, (b) interpret it as an emergency, and (c) assume responsibility for helping. Other factors, including our mood and our similarity to the victim, also affect our willingness to help.
- We are least likely to help if other bystanders are present (the *bystander effect*).

80-2

How do social exchange theory and social norms explain helping behavior?

- *Social exchange theory* is the view that we help others because it is in our own self-interest; in this view, the goal of social behavior is maximizing personal benefits and minimizing costs.
- Others believe that helping results from socialization, in which we are taught guidelines for expected behaviors in social situations, such as the *reciprocity norm* and the *social-responsibility norm*.

80-3

How do social traps and mirror-image perceptions fuel social conflict?

- A *conflict* is a perceived incompatibility of actions, goals, or ideas.
- *Social traps* are situations in which people in conflict pursue their own individual self-interest, harming the collective well-being.
- Individuals and cultures in conflict also tend to form *mirror-image perceptions* that may become *self-fulfilling prophecies*: Each party views the opponent as untrustworthy and evil-intentioned, and itself as an ethical, peaceful victim.

80-4

How can we transform feelings of prejudice, aggression, and conflict into attitudes that promote peace?

- Peace can result when individuals or groups work together to achieve *superordinate* (shared) *goals*.
- Research indicates that four processes—contact, cooperation, communication, and conciliation—help promote peace.

Multiple-Choice Questions

- Which of the following is the best term or phrase for the unselfish concern for the welfare of others?
 - Assuming responsibility
 - Bystander intervention
 - Altruism
 - Bystander effect
 - Diffusion of responsibility
- Which of the following maintains that our social behavior is an exchange process that minimizes costs?
 - Social-responsibility norm
 - Bystander apathy
 - Reciprocity norm
 - Social exchange theory
 - Biopsychosocial hypothesis

3. What do we call a situation in which the conflicting parties, by rationally pursuing their self-interest, become caught in mutually destructive behavior?
 - a. Social trap
 - b. Conflict
 - c. Bystander intervention
 - d. Diffusion of responsibility
 - e. Social-responsibility norm
4. What do we call a belief that leads to its own fulfillment?
 - a. Superordinate goal
 - b. Mirror-image perception
 - c. Enemy perception
 - d. Social trap
 - e. Self-fulfilling prophecy

Practice FRQs

1. According to Darley and Latané, what three things must happen for a bystander to intervene?
2. The author identifies two “enemy perceptions.” Name and describe both.

(4 points)

Answer

1 point: The bystander must notice the event.

1 point: The bystander must interpret the incident as an emergency.

1 point: The bystander must assume responsibility.

AP® Exam Practice Questions

Multiple-Choice Questions

- The enhancement of a group's prevailing tendencies occurs when people within a group discuss an idea that most of them either favor or oppose. What is this tendency called?
 - Group polarization
 - Deindividuation
 - The just-world phenomenon
 - Discrimination
 - Categorization
- Which of the following statements about the foot-in-the-door phenomenon is *false*?
 - People who agree to a small action are less likely to agree to a larger one later.
 - The Chinese army took advantage of this phenomenon in the thought control program they used on prisoners during the Korean War.
 - To get people to agree to something big, start small and build.
 - Succumb to a temptation and you will find the next temptation harder to resist.
 - This phenomenon has been used to boost charitable contributions, blood donations, and product sales.
- According to research on the bystander effect, which of the following people is most likely to stop and help a stranger?
 - Jacob is on his way to a doctor's appointment with his young son.
 - Xavier lives in a crowded city.
 - Malika is in a terrible mood, having just learned that she failed her midterm exam.
 - Ciera just saw a young girl offering her arm to help an older woman cross the street.
 - Mahmood is lost in thought as he walks to work, thinking about his upcoming presentation.
- Believing that your school is better than all the other schools in town is an example of what psychological concept?
 - Ingroup bias
 - Conformity
 - Scapegoat theory
 - Discrimination
 - Groupthink
- People frequently credit or blame either internal dispositions or external situations for others' behavior. What is this tendency called?
 - The foot-in-the-door phenomenon
 - The fundamental attribution error
 - Attribution
 - Social psychology
 - Social thinking
- Researchers have found that people tend to become more hostile in situations when they are exposed to aversive stimuli, such as heat or personal insults. What is the term for this tendency?
 - The proximity effect
 - GRIT
 - The frustration-aggression principle
 - Social scripting
 - Deindividuation
- Galileo's notion that the earth revolved around the sun was in opposition to the widespread beliefs of his day. What social psychological principle is this an example of?
 - Social thinking
 - Group polarization
 - Conformity
 - A stereotype
 - Minority influence
- Physical or verbal behavior intended to hurt or destroy is called
 - the mere exposure effect.
 - hindsight bias.
 - aggression.
 - the just-world phenomenon.
 - the other-race effect.
- What tension occurs when we become aware that our attitudes and actions don't coincide?
 - Role playing
 - The fundamental attribution error
 - Social pressure
 - Social influence
 - Cognitive dissonance

- 10.** Which of the following *least* describes prejudice?
- An unjustifiable attitude toward a group
 - Schemas that influence how we notice and interpret events
 - Preconceived ideas that bias our impressions of others' behavior
 - A physical behavior intended to hurt or destroy
 - Automatic and unconscious thoughts and behaviors
- 11.** Which social psychology principle influences people to perform a task better in the presence of others?
- Compliance
 - Group polarization
 - Social facilitation
 - Conformity
 - Social loafing
- 12.** Becoming less self-conscious and less restrained when in a group situation is referred to as
- social loafing.
 - deindividuation.
 - social facilitation.
 - obedience.
 - cognitive dissonance.
- 13.** If Juan believes Ngoc is annoyed with him, he may snub her, causing her to act in ways that justify his perception. What concept is this an example of?
- Superordinate goals
 - Tension-reduction
 - A social trap
 - A mirror-image perception
 - Self-fulfilling prophecy
- 14.** Which of the following is the most complete definition of conformity?
- Sharing a mood with others
 - Unconsciously mimicking the behaviors and reactions of others
 - Changing thoughts about a situation in order to please an authority figure
 - Adjusting our behavior or thinking toward some group standard
 - Bringing our attitudes in line with our actions
- 15.** Sophia was not sure she would like the new driver of her school bus, but during the year she realized she was looking forward to greeting him in the morning and hearing one of his corny jokes. Which concept best explains her change in perception?
- Similarity
 - Ingroup bias
 - Companionate attraction
 - Social trap
 - Mere exposure effect

Free-Response Questions

1. Abi moved from her small rural hometown to a large city to pursue her singing career. She was hired for an important and popular choral performance. She is nervous but excited about this new opportunity. Explain how the following social psychology factors might affect her experiences in the “big city.”
 - Self-fulfilling prophecy
 - Frustration-aggression model
 - Social facilitation
 - Reciprocity norm

Rubric for Free Response Question 1

1 point: Self-fulfilling prophecy: Abi may think that she is not talented enough to compete with all of the other singers in the performance. Because of her low expectations of herself, she may not perform to the best of her ability. 🔄 Page 812

1 point: Frustration-aggression model: If Abi does not progress to her satisfaction, and experiences frustration as her career stagnates, she may lash out at her colleagues either physically or verbally or even try to railroad others’ careers to further her own. 🔄 Page 791

1 point: Social facilitation: Abi has been singing for a number of years. Because this is a well-practiced activity, Abi’s performance should be enhanced by the presence of others. Because she will have larger crowds in the “big city,” Abi’s performance should improve in front of larger crowds. 🔄 Page 771

1 point: Reciprocity norm: If Abi receives gifts (such as flowers) from the audience, she may be motivated to give an extra effort in her performances. If the audience perceives that Abi is throwing herself completely into her performance and exhausting herself trying to entertain them, they each will be more likely to applaud and cheer because the reciprocity norm indicates we will often return the efforts or feelings of others. 🔄 Page 809

2. Peter and Manuela met in their high school senior year psychology class. They sat near each other and were often partnered during class discussions and group work. They were both on the swim team and often volunteered at the same homelessness prevention shelter. By the end of the year, they became good friends. Later, Manuela and Peter attended the same college, and after graduation they became engaged. When they attended their five-year high school reunion it was obvious to their friends from high school that they were a very happy couple.

Explain the *reward theory of attraction* and give an example to show how each of the following factors may have influenced Manuela and Peter’s developing relationship from high school through college.

- Proximity
- Equity
- Self-disclosure
- Companionate love

(5 points)

3. Dutch is in his first year as a student at a large university. At the urging of some friends, he attended a “pep rally” on the night prior to the football game. At the rally, the marching band played the university’s fight song and Dutch began singing along as they did. The head football coach then gave a rousing speech and Dutch joined with the hundreds of other students to cheer him. Although Dutch had not paid attention to the football team prior to the rally, he enthusiastically participated in the rally, even going so far as to have an image of the team’s mascot painted on his face. The following day, he attended the game and since has become an avid fan of the football team.

Analyze Dutch’s behavior at the rally and afterwards, using each of the following principles of social psychology:

- Peripheral route persuasion
- Central route persuasion
- Automatic mimicry
- Social facilitation
- Deindividuation

Module 81

Influences on Drug Use

Module Learning Objective

81-1

Explain why some people become regular users of consciousness-altering drugs.

81-1

Why do some people become regular users of consciousness-altering drugs?

Drug use by North American youth increased during the 1970s. Then, with increased drug education and a more realistic and deglamorized media depiction of taking drugs, drug use declined sharply. After the early 1990s, the cultural antidrug voice softened, and drugs for a time were again glamorized in some music and films. Consider these marijuana-related trends:

- In the University of Michigan's annual survey of 15,000 U.S. high school seniors, the proportion who believe there is "great risk" in regular marijuana use rose from 35 percent in 1978 to 79 percent in 1991, then retreated to 44 percent in 2012 (Johnston et al., 2013).
- After peaking in 1978, marijuana use by U.S. high school seniors declined through 1992, then rose, but has recently been tapering off (**FIGURE 81.1**). Among Canadian 15- to 24-year-olds, 23 percent report using marijuana monthly, weekly, or daily (Health Canada, 2012).

Figure 81.1

Trends in drug use The percentage of U.S. high school seniors who report having used alcohol, marijuana, or cocaine during the past 30 days declined from the late 1970s to 1992, when it partially rebounded for a few years. (From Johnston et al., 2013.)

For some adolescents, occasional drug use represents thrill seeking. Why, though, do others become regular drug users? In search of answers, researchers have engaged biological, psychological, and social-cultural levels of analysis.

Biological Influences

Some people may be biologically vulnerable to particular drugs. For example, evidence accumulates that heredity influences some aspects of alcohol use problems, especially those appearing by early adulthood (Crabbe, 2002):

- Adopted individuals are more susceptible to alcohol use disorder if one or both biological parents have a history of it.
- Having an identical rather than fraternal twin with alcohol use disorder puts one at increased risk for alcohol problems (Kendler et al., 2002). In marijuana use also, identical twins more closely resemble each other than do fraternal twins.
- Boys who at age 6 are excitable, impulsive, and fearless (genetically influenced traits) are more likely as teens to smoke, drink, and use other drugs (Masse & Tremblay, 1997).
- Researchers have bred rats and mice that prefer alcoholic drinks to water. One such strain has reduced levels of the brain chemical NPY. Mice engineered to *overproduce* NPY are very sensitive to alcohol's sedating effect and drink little (Thiele et al., 1998).
- Researchers have identified genes that are more common among people and animals predisposed to alcohol use disorder, and they are seeking genes that contribute to tobacco addiction (NIH, 2006; Nurnberger & Bierut, 2007). These culprit genes seemingly produce deficiencies in the brain's natural dopamine reward system: While triggering temporary dopamine-produced pleasure, the addictive drugs disrupt normal dopamine balance. Studies of how drugs reprogram the brain's reward systems raise hopes for anti-addiction drugs that might block or blunt the effects of alcohol and other drugs (Miller, 2008; Wilson & Kuhn, 2005).

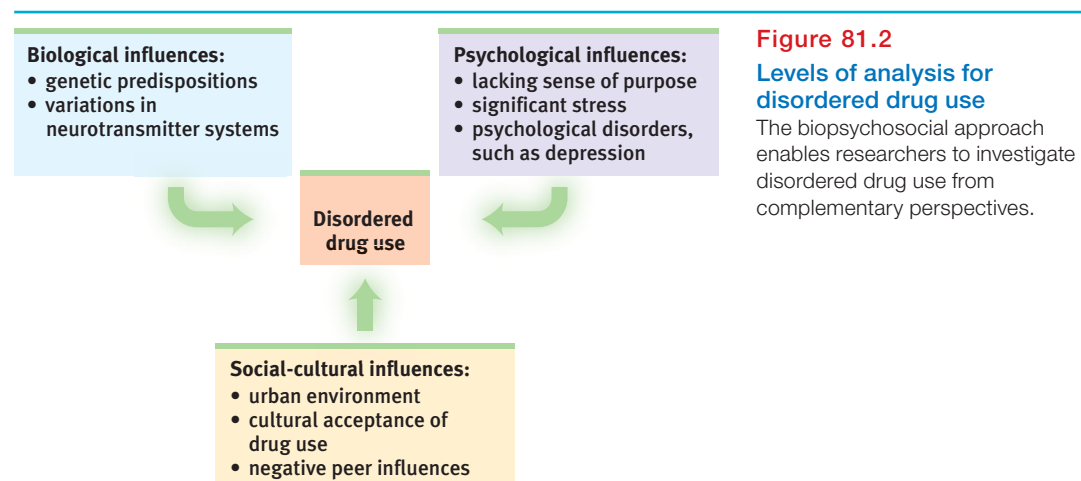

FYI

Warning signs of alcohol use disorder

- Drinking binges
- Craving alcohol
- Use results in unfulfilled work, school, or home tasks
- Failing to honor a resolve to drink less
- Continued use when risky
- Avoiding family or friends when drinking

Psychological and Social-Cultural Influences

Throughout this text, you have seen that biological, psychological, and social-cultural influences interact to produce behavior. So, too, with disordered drug use (**FIGURE 81.2**). One psychological factor that has appeared in studies of youth and young adults is the feeling that life is meaningless and directionless (Newcomb & Harlow, 1986). This feeling is common among school dropouts who subsist without job skills, without privilege, and with little hope.

Sometimes the psychological influence is obvious. Many heavy users of alcohol, marijuana, and cocaine have experienced significant stress or failure and are depressed. Girls with a history of depression, eating disorders, or sexual or physical abuse are at risk for substance addiction. So are youth undergoing school or neighborhood transitions (CASA, 2003; Logan et al., 2002). Collegians who have not yet achieved a clear identity are also at greater risk (Bishop et al., 2005). By temporarily dulling the pain of self-awareness, alcohol and other drugs may offer a way to avoid coping with depression, anger, anxiety, or insomnia. As Unit VI explained, behavior is often controlled more by its immediate consequences than by its later ones.

Especially for teenagers, drug use can have social roots. For example, teens are exposed to smoking in movies. Those with a lot of exposure are three times as likely as other teens to try smoking and become smokers. And that correlation is not a result of personality, parenting style, or family economics, which researchers controlled for (Heatherton & Sargent, 2009). Most teen drinking is done for social reasons, not as a way to cope with problems (Kuntsche et al., 2005). When young unmarried adults leave home, alcohol and other drug use increases; when they marry and have children, it decreases (Bachman et al., 1997).

Rates of drug use also vary across cultural and ethnic groups. One survey of 100,000 teens in 35 European countries found that marijuana use in the prior 30 days ranged from zero to 1 percent in Romania and Sweden to 20 to 22 percent in Britain, Switzerland, and France (ESPAD, 2003). Independent U.S. government studies of drug use in households nationwide and among high schoolers in all regions reveal that African-American teens have sharply lower rates of drinking, smoking, and cocaine use (Johnston et al., 2007). Alcohol and other drug addiction rates have also been low among those actively religious, and extremely low among Orthodox Jews, Mormons, the Amish, and Mennonites (Trimble, 1994; Yeung et al., 2009). Relatively drug-free small towns and rural areas tend to constrain any genetic predisposition to drug use (Legrand et al., 2005). So does active parental monitoring (Lac & Crano, 2009). For those whose genetic predispositions nudge them toward substance use, cities offer more opportunities and less supervision.

Whether in cities or rural areas, peers influence attitudes about drugs. They also throw the parties and provide (or don't provide) the drugs. If an adolescent's friends use drugs, the odds are that he or she will, too. If the friends do not, the opportunity may not even arise. Teens who come from happy families, who do not begin drinking before age 15, and who do well in school tend not to use drugs, largely because they rarely associate with those who do (Bachman et al., 2007; Hingson et al., 2006; Odgers et al., 2008).

Peer influence is more than what friends do or say. Adolescents' expectations—what they *believe* friends are doing and favoring—influence their behavior (Vitória et al., 2009). One study surveyed sixth graders in 22 U.S. states. How many believed their friends had smoked marijuana? About 14 percent. How many of those friends acknowledged doing so? Only 4 percent (Wren, 1999). University students are not immune to such misperceptions: Drinking dominates social occasions partly because students overestimate their fellow students' enthusiasm for alcohol and underestimate their views of its risks (Prentice & Miller, 1993; Self, 1994) (**TABLE 81.1**). When students' overestimates of peer drinking are corrected, alcohol use often subsides (Moreira et al., 2009).

People whose beginning use of drugs was influenced by their peers are more likely to stop using when friends stop or their social network changes (Kandel & Raveis, 1989). One study that followed 12,000 adults over 32 years found that smokers tend to quit in clusters (Christakis & Fowler, 2008). Within a social network, the odds of a person's quitting increased when a spouse, friend, or co-worker stopped smoking. Similarly, most soldiers who became drug addicted while in Vietnam ceased their drug use after returning home (Robins et al., 1974).

FYI

Percentage of adults drinking weekly or more varies by country:

United States	30%
Canada	40%
Britain	58%

(Gallup Poll, from Moore, 2006)

SNAPSHOTS

Table 81.1 Facts About “Higher” Education

- College and university students drink more alcohol than their nonstudent peers and exhibit 2.5 times the general population’s rate of substance abuse.
- Fraternity and sorority members report nearly twice the binge drinking rate of nonmembers.
- Since 1993, campus smoking rates have declined, alcohol use has been steady, and abuse of prescription opioids, stimulants, tranquilizers, and sedatives has increased, as has marijuana use.

Source: NCASA, 2007.

As always with correlations, the traffic between friends’ drug use and our own may be two-way: Our friends influence us. Social networks matter. But we also select as friends those who share our likes and dislikes.

What do the findings on drug use suggest for drug prevention and treatment programs? Three channels of influence seem possible:

- Educate young people about the long-term costs of a drug’s temporary pleasures.
- Help young people find other ways to boost their self-esteem and purpose in life.
- Attempt to modify peer associations or to “inoculate” youths against peer pressures by training them in refusal skills.

People rarely abuse drugs if they understand the physical and psychological costs, feel good about themselves and the direction their lives are taking, and are in a peer group that disapproves of using drugs. These educational, psychological, and social-cultural factors may help explain why 26 percent of U.S. high school dropouts, but only 6 percent of those with a postgraduate education, report smoking (CDC, 2011).

Before You Move On

▶ **ASK YOURSELF**

Drinking dominates parties when students overestimate other students’ enthusiasm for alcohol. Do you think such misperceptions exist at your high school? How might you find out?

▶ **TEST YOURSELF**

Studies have found that people who begin drinking in their early teens are much more likely to exhibit alcohol use disorder than those who begin at age 21 or after. What possible explanations might there be for this correlation between early use and later abuse?

Answers to the Test Yourself questions can be found in Appendix E at the end of the book.

Module 81 Review

81-1

Why do some people become regular users of consciousness-altering drugs?

- Some people may be biologically vulnerable to particular drugs, such as alcohol.
- Psychological factors (such as stress, depression, and hopelessness) and social factors (such as peer pressure) combine to lead many people to experiment with—and sometimes become addicted to—drugs. Cultural and ethnic groups have differing rates of drug use.
- Each type of influence—biological, psychological, and social-cultural—offers a possible path for drug prevention and treatment programs.

Multiple-Choice Questions

1. Which of the following is true of 6-year-old boys who are more likely to use drugs when they become teenagers?
 - a. They are introverted.
 - b. They have difficulty learning to read.
 - c. They are prone to temper tantrums.
 - d. They are isolated from their peers.
 - e. They are excitable, impulsive, and fearless.
2. Which of the following is most clearly a biological influence on disordered drug use?
 - a. Significant stress
 - b. Variations in neurotransmitter systems
 - c. An urban environment
 - d. Peer influence
 - e. A lack of purpose
3. Which of the following statements most accurately reflects the relationship between drinking and expectations among U.S. college students? The students
 - a. typically overestimate the percentage of fellow students who drink.
 - b. accurately estimate the percentage of fellow students who drink.
 - c. tend to slightly underestimate the percentage of fellow students who drink.
 - d. tend to greatly underestimate the percentage of fellow students who drink.
 - e. tend to be inaccurate in their estimates of the percentage of fellow students who drink, but there is no clear pattern to their inaccuracies.

Practice FRQ

1. Briefly explain one biological, one psychological, and one social-cultural influence on drug use.

(3 points)

Module 82

Psychology at Work

Module Learning Objectives

- 82-1** Explain the concept of *flow*, and identify three subfields of industrial-organizational psychology.
- 82-2** Describe how personnel psychologists help organizations with employee selection, work placement, and performance appraisal.
- 82-3** Define *achievement motivation*, and describe the role of organizational psychologists.
- 82-4** Describe some effective leadership techniques.
- 82-5** Describe human factors psychologists' work to create user-friendly machines and work settings.

Psychology at Work

- 82-1** What is *flow*, and what are the three subfields of industrial-organizational psychology?

For most of us, work is life's biggest single waking activity. To live is to work. Work helps satisfy several levels of need identified in Maslow's hierarchy of needs. Work supports us. Work connects us. Work defines us. Meeting someone for the first time, and wondering "Who are you?" we may ask, "So, what do you do?"

Amy Wrzesniewski and her colleagues (1997, 2001) have identified person-to-person variations in people's attitudes toward their work. Across various occupations, some people view their work as a *job*, an unfulfilling but necessary way to make money. Others view their work as a *career*, an opportunity to advance from one position to a better position. The rest—those who view their work as a *calling*, a fulfilling and socially useful activity—report the highest satisfaction with their work and with their lives.

This finding would not surprise Mihaly Csikszentmihalyi (1990, 1999). He has observed that people's quality of life increases when they are purposefully engaged. Between the anxiety of being overwhelmed and stressed, and the apathy of being underwhelmed and bored, lies a zone in which people experience **flow**. Can you recall being in a zoned-out flow state while playing a video game or text messaging? If so, then perhaps you can sympathize with the two Northwest Airlines pilots who in 2009 were so focused on their laptops that they missed Earth-to-pilot messages from their control tower. The pilots flew 150 miles past their Minneapolis destination—and lost their jobs.

FYI

Sometimes, notes Gene Weingarten (2002), a humor writer knows "when to just get out of the way." Here are some sample job titles from the U.S. Department of Labor *Dictionary of Occupational Titles*: Animal impersonator, human projectile, banana ripening-room supervisor, impregnator, impregnator helper, dope sprayer, finger waver, rug scratcher, egg smeller, bottom buffer, cookie breaker, brain picker, hand pouncer, bosom presser, and mother repairer.

flow a completely involved, focused state of consciousness, with diminished awareness of self and time, resulting from optimal engagement of one's skills.

FYI

Have you ever noticed that when you are immersed in an activity, time flies? And that when you are watching the clock, it seems to move more slowly? French researchers have confirmed that the more we attend to an event's duration, the longer it seems to last (Couli et al., 2004).

industrial-organizational (I/O) psychology the application of psychological concepts and methods to optimizing human behavior in workplaces.

personnel psychology an I/O psychology subfield that focuses on employee recruitment, selection, placement, training, appraisal, and development.

organizational psychology an I/O psychology subfield that examines organizational influences on worker satisfaction and productivity and facilitates organizational change.

human factors psychology an I/O psychology subfield that explores how people and machines interact and how machines and physical environments can be made safe and easy to use.

FYI

The editorial team that supports the creation of this book and its teaching resources reflects a modern trend toward working together remotely. Project manager Kathryn Brownson is in Michigan, editor Christine Brune is in Alaska, publisher Kevin Feyen is in New York, editor Dora Figueiredo is in New Jersey, editor Nancy Fleming is in Massachusetts, publisher Ann Heath is in Oregon, development director Tracey Kuehn is in New York, editor Trish Morgan is in Alberta, and editor Betty Probert and manuscript developer Don Probert are in Florida.

Disrupted flow Internet-related distractions can disrupt flow. It takes time to refocus mental concentration after the distraction of an e-mail or a text.

Erik Isakson/Tetra Images/Corbis

Csikszentmihalyi [chick-SENT-me-hi] formulated the flow concept after studying artists who spent hour after hour painting or sculpting with enormous concentration. Immersed in a project, they worked as if nothing else mattered, and then, when finished, they promptly forgot about it. The artists seemed driven less by the external rewards of producing art—money, praise, promotion—than by the intrinsic rewards of creating the work.

Csikszentmihalyi's later observations—of dancers, chess players, surgeons, writers, parents, mountain climbers, sailors, and farmers; of Australians, North Americans, Koreans, Japanese, and Italians; of people from their teens to their golden years—confirmed an overriding principle: It's exhilarating to flow with an activity that fully engages our skills. Flow experiences boost our sense of self-esteem, competence, and well-being. Idleness may sound like bliss, but purposeful work enriches our lives. Busy people are happier (Hsee et al., 2010; Robinson & Martin, 2008). One research team interrupted people on about a quarter-million occasions (using a smart-phone app), and found people's minds wandering 47 percent of the time. They were, on average, happier when *not* mind-wandering (Killingworth & Gilbert, 2010).

In many nations, work has been changing, from farming to manufacturing to *knowledge work*. More and more work is outsourced to temporary employees and consultants or done by telecommuters who communicate electronically from virtual workplaces in remote locations. As work changes, will our attitudes toward our work also change? Will our satisfaction with work increase or decrease? Will the *psychological contract*—the sense of mutual obligations between workers and employers—become more or less trusting and secure? These are among the questions that fascinate psychologists who study work-related behavior.

Industrial-organizational (I/O) psychology applies psychology's principles to the workplace (see Close-up: I/O Psychology at Work). Here we consider three of I/O psychology's subfields:

- **Personnel psychology** applies psychology's methods and principles to selecting and evaluating workers. Personnel psychologists match people with jobs, by identifying and placing well-suited candidates.
- **Organizational psychology** considers how work environments and management styles influence worker motivation, satisfaction, and productivity. Organizational psychologists modify jobs and supervision in ways that boost morale and productivity.
- **Human factors psychology** explores how machines and environments can be optimally designed to fit human abilities. Human factors psychologists study people's natural perceptions and inclinations to create user-friendly machines and work settings.

Close-up**I/O Psychology at Work**

As scientists, consultants, and management professionals, industrial-organizational psychologists are found working in varied areas:

PERSONNEL PSYCHOLOGY**Selecting and placing employees**

- Developing and validating assessment tools for selecting, placing, and promoting workers
- Analyzing job content
- Optimizing worker placement

Training and developing employees

- Identifying needs
- Designing training programs
- Evaluating training programs

Appraising performance

- Developing criteria
- Measuring individual performance
- Measuring organizational performance

ORGANIZATIONAL PSYCHOLOGY**Developing organizations**

Personnel Psychology**82-2**

How do personnel psychologists help organizations with employee selection, work placement, and performance appraisal?

Psychologists can assist organizations at various stages of selecting and assessing employees. They may help identify needed job skills, decide upon selection methods, recruit and evaluate applicants, introduce and train new employees, and appraise their performance.

Harnessing Strengths

As a new AT&T human resource executive, psychologist Mary Tenopyr (1997) was assigned to solve a problem: Customer-service representatives were failing at a high rate. After concluding that many of the hires were ill-matched to the demands of their new job, Tenopyr developed a new selection instrument:

1. She asked new applicants to respond to various questions (without as yet making any use of their responses).
2. She followed up later to assess which of the applicants excelled on the job.
3. She identified the individual items on the earlier test that best predicted who would succeed.

The happy result of her data-driven work was a new test that enabled AT&T to identify likely-to-succeed customer-service representatives. Personnel selection techniques such as this one aim to match people's strengths with work that enables them and their organization to flourish. Marry the strengths of people with the tasks of organizations, and the result is often prosperity and profit.

Alvin Langdon Coburn/George Eastman House/Getty Images

Artistic strengths At age 21, Henri Matisse was a sickly and often depressed lawyer's clerk. When his mother gave him a box of paints to cheer him up one day, he felt the darkness lift and his energy surge. He began to fill his days with painting and drawing and went on to art school and a life as one of the world's great painters. For Matisse, doing art felt like "a comfortable armchair." That is how exercising our strengths often feels.

Your strengths are any enduring qualities that can be productively applied. Are you naturally curious? Persuasive? Charming? Persistent? Competitive? Analytical? Empathic? Organized? Articulate? Neat? Mechanical? Any such trait, if matched with suitable work, can function as a strength (Buckingham, 2007). (See Close-up: Discovering Your Strengths.)

Gallup researchers Marcus Buckingham and Donald Clifton (2001) have argued that the first step to a stronger organization is instituting a strengths-based selection system. Thus, as a manager, you would first identify a group of the most effective people in any role—the ones you would want to hire more of—and compare their strengths with those of a group of the least effective people in that role. In defining these groups, you would try to measure performance as objectively as possible. In one Gallup study of more than 5000 telecommunications customer-service representatives, those evaluated most favorably by their managers were strong in "harmony" and "responsibility," while those actually rated most effective by customers were strong in energy, assertiveness, and eagerness to learn.

An example: If you needed to hire new people in software development, and you had discovered that your best software developers are analytical, disciplined, and eager to learn, you would focus employment ads less on experience than on the identified strengths. Thus "Do you take a logical and systematic approach to problem solving [*analytical*]? Are you a perfectionist who strives for timely completion of your projects [*disciplined*]? Do you want to master Java, C++, and PHP [*eager to learn*]? If you can say *yes* to these questions, then please call . . ."

Identifying people's strengths and matching strengths to work is a first step toward workplace effectiveness. Personnel managers use various tools to assess applicants' strengths and decide who is best suited to the job (Sackett & Lievens, 2008). In Module 59, we explored personality tests and "assessment centers" that enable observations of behaviors on simulated job tasks. And in Module 61, we saw how psychologists assess candidates using ability tests. Here we'll consider the job interview.

Close-up

Discovering Your Strengths

You can use some of the techniques personnel psychologists have developed to identify your own strengths and pinpoint types of work that will likely prove satisfying and successful. Buckingham and Clifton (2001) have suggested asking yourself these questions:

- What activities give me pleasure? (Bringing order out of chaos? Playing host? Helping others? Challenging sloppy thinking?)
- What activities leave me wondering, "When can I do this again?" (Rather than, "When will this be over?")
- What sorts of challenges do I relish? (And which do I dread?)
- What sorts of tasks do I learn easily? (And which do I struggle with?)

Some people find themselves in flow—their skills engaged and time flying—when teaching or selling or writing or cleaning or consoling or creating or repairing. If an activity feels good, if it comes easily, if you look forward to it, then look deeper and see your strengths at work.

Satisfied and successful people devote far less time to correcting their deficiencies than to accentuating their strengths. Top performers are "rarely well rounded," Buckingham and Clifton found (p. 26). Instead, they have sharpened their existing skills. Given the persistence of our traits and temperaments, we should focus not on our deficiencies, but rather on identifying and employing our talents. There may be limits to the benefits of assertiveness training if you are extremely shy, of public speaking courses if you tend to be nervous and soft-spoken, or of drawing classes if you express your artistic side in stick figures. To discover and develop your strengths, might you try out for a play or a sport, join a club, or volunteer in your community?

Identifying your talents can help you recognize the activities you learn quickly and find absorbing. Knowing your strengths, you can develop them further. FYI: For a free (it only requires registration) assessment of your strengths, visit www.authentic happiness.sas.upenn.edu and select "Brief Strengths Test."

DO INTERVIEWS PREDICT PERFORMANCE?

Interviewers tend to feel confident in their ability to predict long-term job performance from an unstructured, get-acquainted interview. What's therefore shocking is how error-prone those predictions are. Whether predicting job or graduate school success, interviewers' judgments are weak predictors. From their review of 85 years of personnel-selection research, I/O psychologists Frank Schmidt and John Hunter (1998; Schmidt, 2002) determined that for all but less-skilled jobs, general mental ability best predicts on-the-job performance. Subjective overall evaluations from informal interviews are more useful than handwriting analysis (which is worthless). But informal interviews are less informative than aptitude tests, work samples, job knowledge tests, and past job performance. If there's a contest between what our gut tells us about someone and what test scores, work samples, and past performance tell us, we should distrust our gut.

THE INTERVIEWER ILLUSION

Richard Nisbett (1987) has labeled interviewers' overrating their discernment as the *interviewer illusion*. "I have excellent interviewing skills, so I don't need reference checking as much as someone who doesn't have my ability to read people," is a comment sometimes heard by I/O consultants. Four factors explain this gap between interviewers' overconfidence and the resulting reality:

- *Interviews disclose the interviewee's good intentions, which are less revealing than habitual behaviors* (Ouellette & Wood, 1998). Intentions matter. People can change. But the best predictor of the person we will be is the person we have been. Compared with work-avoiding university students, those who engage in their tasks are more likely, a decade and more later, to be engaged workers (Salmela-Aro et al., 2009). Educational attainments predict job performance partly because people who have shown up for school each day and done their tasks also tend to show up for work and do their tasks (Ng & Feldman, 2009). Wherever we go, we take ourselves along.
- *Interviewers more often follow the successful careers of those they have hired than the successful careers of those they have rejected and lost track of.* This missing feedback prevents interviewers from getting a reality check on their hiring ability.
- *Interviewers presume that people are what they seem to be in the interview situation.* As Module 74 explained, when meeting others, we discount the enormous influence of varying situations and mistakenly presume that what we see is what we will get. But mountains of research on everything from chattiness to conscientiousness reveal that how we behave reflects not only our enduring traits, but also the details of the particular situation (such as wanting to impress in a job interview).
- *Interviewers' preconceptions and moods color how they perceive interviewees' responses* (Cable & Gilovich, 1998; Macan & Dipboye, 1994). If interviewers instantly like a person who perhaps is similar to themselves, they may interpret the person's assertiveness as indicating "confidence" rather than "arrogance." If told certain applicants have been prescreened, interviewers are disposed to judge them more favorably.

Traditional *unstructured interviews* do provide a sense of someone's personality—their expressiveness, warmth, and verbal ability, for example. But unstructured interviews also give interviewees considerable power to control the impression they are making in the interview situation (Barrick et al., 2009). The interview may thus create a false impression of the person's behavior toward others in different situations. Hoping to improve prediction and selection, personnel psychologists have put people in simulated work situations, scoured sources for information on past performance, aggregated evaluations from multiple interviews, administered tests, and developed job-specific interviews.

"Interviews are a terrible predictor of performance." -LASZLO BOCK, GOOGLE'S VICE PRESIDENT, PEOPLE OPERATIONS, 2007

"Between the idea and reality . . . falls the shadow." -T. S. ELIOT, *THE HOLLOW MEN*, 1925

structured interviews

an interview process that asks the same job-relevant questions of all applicants, each of whom is rated on established scales.

STRUCTURED INTERVIEWS

Unlike casual conversation aimed at getting a feel for someone, **structured interviews** offer a disciplined method of collecting information. A personnel psychologist may analyze a job, script questions, and train interviewers. The interviewers then put the same questions, in the same order, to all applicants, and rate each applicant on established scales.

In an unstructured interview, someone might ask, “How organized are you?” “How well do you get along with people?” or “How do you handle stress?” Street-smart applicants know how to score high: “Although I sometimes drive myself too hard, I handle stress by prioritizing and delegating, and by making sure I leave time for sleep and exercise.”

By contrast, structured interviews pinpoint strengths (attitudes, behaviors, knowledge, and skills) that distinguish high performers in a particular line of work. The process includes outlining job-specific situations and asking candidates to explain how they would handle them, and how they handled similar situations in their prior employment. “Tell me about a time when you were caught between conflicting demands, without time to accomplish both. How did you handle that?”

To reduce memory distortions and bias, the interviewer takes notes and makes ratings as the interview proceeds and avoids irrelevant and follow-up questions. The structured interview therefore feels less warm, but that can be explained to the applicant: “This conversation won’t typify how we relate to each other in this organization.”

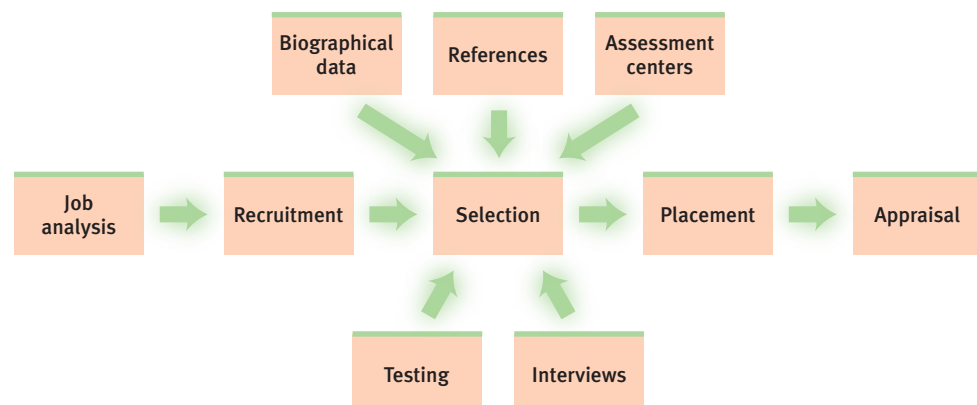

A review of 150 findings revealed that structured interviews had double the predictive accuracy of unstructured seat-of-the-pants interviews (Schmidt & Hunter, 1998; Wiesner & Cronshaw, 1988). Structured interviews also reduce bias, such as against overweight applicants (Kutcher & Bragger, 2004). Thanks partly to its greater reliability and partly to its job-analysis focus, the predictive power of one structured interview is roughly equal to that of the average judgment from three or four unstructured interviews (Huffcutt et al., 2001; Schmidt & Zimmerman, 2004).

If, instead, we let our intuitions bias the hiring process, notes Malcolm Gladwell (2000, p. 86), then “all we will have done is replace the old-boy network, where you hired your nephew, with the new-boy network, where you hire whoever impressed you most when you shook his hand. Social progress, unless we’re careful, can merely be the means by which we replace the obviously arbitrary with the not so obviously arbitrary.”

To recap, personnel psychologists assist organizations in analyzing jobs, recruiting well-suited applicants, selecting and placing employees, and appraising their performance (**FIGURE 82.1**)—the topic we turn to next.

Figure 82.1**Personnel psychologists’ tasks**

Personnel psychologists consult in human resource activities, from job definition to employee appraisal.

Appraising Performance

Performance appraisal serves organizational purposes: It helps decide who to retain, how to appropriately reward and pay people, and how to better harness employee strengths, sometimes with job shifts or promotions. Performance appraisal also serves individual purposes: Feedback affirms workers' strengths and helps motivate needed improvements.

Performance appraisal methods include

- *checklists* on which supervisors simply check specific behaviors that describe the worker ("always attends to customers' needs," "takes long breaks").
- *graphic rating scales* on which a supervisor checks, perhaps on a five-point scale, how often a worker is dependable, productive, and so forth.
- *behavior rating scales* on which a supervisor checks scaled behaviors that describe a worker's performance. If rating the extent to which a worker "follows procedures," the supervisor might mark the employee somewhere between "often takes shortcuts" and "always follows established procedures" (Levy, 2003).

In some organizations, performance feedback comes not only from supervisors but also from all organizational levels. If you join an organization that practices *360-degree feedback* (FIGURE 82.2), you will rate yourself, your manager, and your other colleagues, and you will be rated by your manager, other colleagues, and customers (Green, 2002). The net result is often more open communication and more complete appraisal.

Performance appraisal, like other social judgments, is vulnerable to bias (Murphy & Cleveland, 1995). *Halo errors* occur when one's overall evaluation of an employee, or of a personal trait such as friendliness, biases ratings of specific work-related behaviors, such as reliability. *Leniency* and *severity errors* reflect evaluators' tendencies to be either too easy or too harsh on everyone. *Recency errors* occur when raters focus only on easily remembered recent behavior. By using multiple raters and developing objective, job-relevant performance measures, personnel psychologists seek to support their organizations while also helping employees perceive the appraisal process as fair.

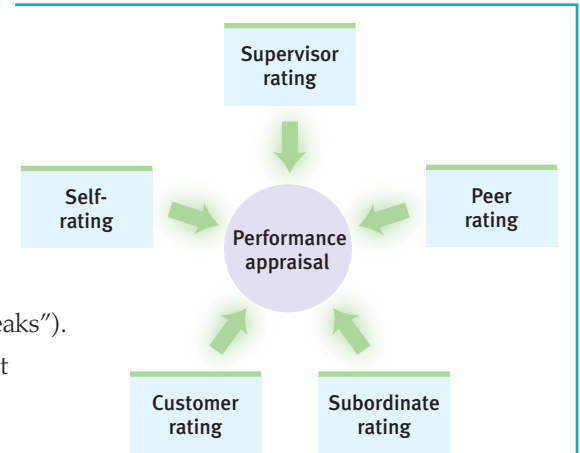

Figure 82.2
360-degree feedback

With multisource 360-degree feedback, our knowledge, skills, and behaviors are rated by ourselves and surrounding others. Teachers, for example, may be rated by students, their principal, and their colleagues. After receiving all these ratings, teachers discuss the 360-degree feedback with their principal.

Before You Move On

▶ ASK YOURSELF

What have you learned about your own strengths and about the kind of career you might see yourself pursuing?

▶ TEST YOURSELF

A human resources director explains to you that "I don't bother with tests or references. It's all about the interview." Based on I/O psychology research, what concerns does this raise?

Answers to the Test Yourself questions can be found in Appendix E at the end of the book.

Organizational Psychology: Motivating Achievement

82-3

What is *achievement motivation*? What is the role of organizational psychologists?

The appraisal of work and the matching of talents to work matter, but so does overall motivation. Before considering how organizational psychologists assist with efforts to motivate employees and keep them engaged, let's take a closer look at why any employee might want to pursue high standards or difficult goals.

“Genius is 1% inspiration and 99% perspiration.” -THOMAS EDISON (1847–1931)

achievement motivation

a desire for significant accomplishment, for mastery of skills or ideas, for control, and for attaining a high standard.

grit in psychology, grit is passion and perseverance in the pursuit of long-term goals.

Calum’s road: What grit can accomplish

Having spent his life on the Scottish island of Raasay, farming a small patch of land, tending its lighthouse, and fishing, Malcolm (“Calum”) MacLeod (1911–1988) felt anguished. His local government repeatedly refused to build a road that would enable vehicles to reach his north end of the island. With the once-flourishing population there having dwindled to two—MacLeod and his wife—he responded with heroic determination. One spring morning in 1964, MacLeod, then in his fifties, gathered an ax, a chopper, a shovel, and a wheelbarrow. By hand, he began to transform the existing footpath into a 1.75-mile road (Miers, 2009).

“With a road,” a former neighbor explained, “he hoped new generations of people would return to the north end of Raasay,” restoring its culture (Hutchinson, 2006). Day after day he worked through rough hillsides, along hazardous cliff faces, and over peat bogs. Finally, 10 years later, he completed his supreme achievement. The road, which the government has since surfaced, remains a visible example of what vision plus determined grit can accomplish. It bids us each to ponder: What “roads”—what achievements—might we, with sustained effort, build in the years before us?

Grit

Think of someone you know who strives to succeed by excelling at any task where evaluation is possible. Now think of someone who is less driven. Psychologist Henry Murray (1938) defined the first person’s **achievement motivation** as a desire for significant accomplishment, for mastering skills or ideas, for control, and for attaining a high standard.

As you might expect from their persistence and eagerness for realistic challenges, people with high achievement motivation do achieve more. One study followed the lives of 1528 California children whose intelligence test scores were in the top 1 percent. Forty years later, when researchers compared those who were most and least successful professionally, they found a motivational difference. Those most successful were more ambitious, energetic, and persistent. As children, they had more active hobbies. As adults, they participated in more groups and favored being sports participants to being spectators (Goleman, 1980). Gifted children are able learners. Accomplished adults are tenacious doers. Most of us are energetic doers when starting and finishing a project. It’s easiest—have you noticed?—to “get stuck in the middle,” which is when high achievers keep going (Bonezzi et al., 2011).

In other studies of both secondary school and university students, self-discipline has been a better predictor of school performance, attendance, and graduation honors than intelligence scores have been. When combined with a positive enthusiasm, sustained, gritty effort predicts success for teachers, too—with their students making good academic progress (Duckworth et al., 2009). “Discipline outdoes talent,” concluded researchers Angela Duckworth and Martin Seligman (2005, 2006).

Discipline also refines talent. By their early twenties, top violinists have accumulated some 10,000 lifetime practice hours—double the practice time of other violin students aiming to be teachers (Ericsson, 2001, 2006, 2007). Researchers report a *10-year rule*: World-class experts in a field typically have invested 10 years and at least 10,000 hours to “intense, daily practice” (Ericsson, 2002, 2007; Simon & Chase, 1973). A study of outstanding scholars, athletes, and artists found that all were highly motivated and self-disciplined, willing to dedicate hours every day to the pursuit of their goals (Bloom, 1985). These superstar achievers were distinguished not so much by their extraordinary natural talent as by their extraordinary daily discipline.

What distinguishes extremely successful individuals from their equally talented peers, notes Duckworth, is **grit**—passionate dedication to an ambitious, long-term goal. Although intelligence is distributed like a bell curve, achievements are not. That tells us that achievement

From Calum’s Road by Roger Hutchinson, reproduced courtesy of Britinn Ltd.

involves much more than raw ability. That is why organizational psychologists seek ways to engage and motivate ordinary people doing ordinary jobs. And that is why training students in “hardiness”—resilience under stress—leads to better grades (Maddi et al., 2009).

Satisfaction and Engagement

Partly because work is such a big part of life, I/O psychologists study employee satisfaction. Satisfaction with work feeds satisfaction with life (Bowling et al., 2010; and see Close-up: Doing Well While Doing Good—“The Great Experiment”). Moreover, as we saw in Module 29, decreased job stress feeds improved health.

Satisfied employees also contribute to successful organizations. Positive moods at work enhance creativity, persistence, and helpfulness (Brief & Weiss, 2002; Kaplan et al., 2009). Are engaged, happy workers also less often absent? Less likely to quit? Less prone to theft? More punctual? More productive? Conclusive evidence of satisfaction’s benefits is, some have said, the Holy Grail of I/O psychology. Statistical digests of prior research have found a modest positive correlation between individual job satisfaction and performance (Judge et al., 2001; Ng et al., 2009; Parker et al., 2003). In one analysis of 4500 employees at 42 British manufacturing companies, the most productive workers tended to be those in satisfying work environments (Patterson et al., 2004). But does satisfaction *produce* better job performance?

“The only place success comes before work is in the dictionary.”
-FORMER GREEN BAY PACKERS
FOOTBALL COACH VINCE LOMBARDI

Close-up

Doing Well While Doing Good—“The Great Experiment”

At the end of the 1700s, the New Lanark, Scotland, cotton mill had more than 1000 workers. Many were children drawn from Glasgow’s poorhouses. They worked 13-hour days and lived in grim conditions. Their education and sanitation were neglected. Theft and drunkenness were commonplace. Most families occupied just one room.

On a visit to Glasgow, Welsh-born Robert Owen—an idealistic young cotton-mill manager—chanced to meet and fall in love with the mill owner’s daughter. After their wedding, Owen, with several partners, purchased the mill and on the first day of the 1800s took control as its manager. Before long, he began what he said was “the most important experiment for the happiness of the human race that had yet been instituted at any time in any part of the world” (Owen, 1814). The exploitation of child and adult labor was, he observed, producing unhappy and inefficient workers. Believing that better working and living conditions could pay economic dividends, he undertook numerous innovations: a nursery for preschool children, education for older children (with encouragement rather than corporal punishment), Sundays off, health care, paid sick days, unemployment pay for days when the mill could not operate, and a company store selling goods at reduced prices.

Owen also innovated a goals- and worker-assessment program that included detailed records of daily productivity and costs. By each employee’s workstation, one of four colored boards indicated that person’s performance for the previous day. Owen could walk through the mill and at a glance see how individuals were performing. There was, he said, “no beating, no abusive language. . . . I merely looked at the person and then at the [color]. . . . I could at once see by the expression [which color] was shown.”

The commercial success that followed was essential to sustaining what became a movement toward humanitarian reforms. By 1816, with decades of profitability still ahead, Owen believed he had demonstrated “that society may be formed so as to exist without crime, without poverty, with health greatly improved, with little if any misery, and with intelligence and happiness increased a hundredfold.” Although his Utopian vision has not been fulfilled, Owen’s great experiment did lay the groundwork for employment practices that have today become accepted in much of the world.

Courtesy of New Lanark Mills World Heritage Site

The great experiment New Lanark Mills, which today is preserved as a World Heritage Site (www.newlanark.org), provided an influential demonstration of how industries could do well while doing good. In its heyday, New Lanark was visited by many European royals and reformers who came to observe its vibrant workforce and prosperous business.

An engaged employee Mohamed Mamow, left, is joined by his employer in saying the Pledge of Allegiance as he becomes a U.S. citizen. Mamow and his wife met in a Somali refugee camp and now are parents of five children, whom he supports by working as a machine operator. Mindful of his responsibility—"I don't like to lose my job. I have a responsibility for my children and my family"—he arrives for work a half hour early and tends to every detail on his shift. "He is an extremely hard-working employee," noted his employer, and "a reminder to all of us that we are really blessed" (Roelofs, 2010).

DARREN GREEN/Grand Rapids Press/Landov

The debate continues, with one analysis of past research indicating that satisfaction and performance correlate because both reflect job self-esteem ("I matter around here") and a sense that efforts control rewards (Bowling, 2007).

Nevertheless, some organizations do have a knack for cultivating more engaged and productive employees. In the United States, the *Fortune* "100 Best Companies to Work For" have also produced markedly higher-than-average returns for their investors (Fulmer et al., 2003). Other positive data come from the biggest-ever I/O study, an analysis of Gallup data from more than 198,000 employees in nearly 8000 business units of 36 large companies (including some 1100 bank branches, 1200 stores, and 4200 teams or departments). James Harter, Frank Schmidt, and Theodore Hayes (2002) explored correlations between various measures of organizational success and *employee engagement*—the extent of workers' involvement, enthusiasm, and identification with their organizations (**TABLE 82.1**). They found that engaged workers (compared with disengaged workers who are just putting in time) know what's expected of them, have what they need to do their work, feel fulfilled in their work, have regular opportunities to do what they do best, perceive that they are part of something significant, and have opportunities to learn and develop. They also found that business units with engaged employees have more loyal customers, less turnover, higher productivity, and greater profits.

Table 82.1 Three Types of Employees

Engaged: working with passion and feeling a profound connection to their company or organization.

Not engaged: putting in the time but investing little passion or energy into their work.

Actively disengaged: unhappy workers undermining what their colleagues accomplish.

Source: Adapted from Gallup via Crabtree, 2005.

But what causal arrows explain this correlation between business success and employee morale and engagement? Does success boost morale, or does high morale boost success? In a follow-up longitudinal study of 142,000 workers, Harter and his colleagues (2010) found that over time, employee attitudes predicted future business success (more than the other way around). Another analysis compared companies with top-quartile versus below-average employee engagement levels. Over a three-year period, earnings grew 2.6 times faster for the companies with highly engaged workers (Ott, 2007).

Managing Well

82-4 What are some effective leadership techniques?

Every leader dreams of managing in ways that enhance people's satisfaction, engagement, and productivity and their organization's success. Effective leaders harness job-relevant strengths, set goals, and choose an appropriate leadership style.

HARNESSING JOB-RELEVANT STRENGTHS

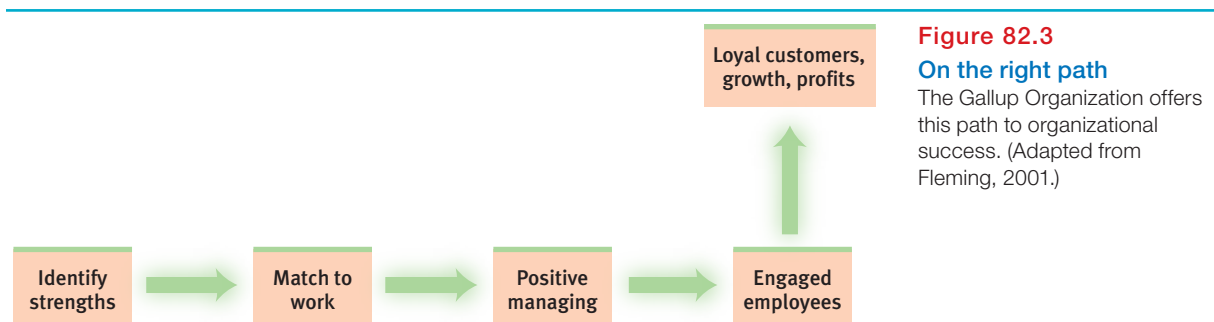

"The major challenge for CEOs over the next 20 years will be the effective deployment of human assets," observed Marcus Buckingham (2001). That challenge is "about psychology. It's about getting [individuals] to be more productive, more focused, more fulfilled than [they were] yesterday." To do so, he and others have maintained, effective leaders want first to select the right people. Then, they aim to discern their employees' natural talents, adjust their work roles to suit their talents, and develop those talents into great strengths (**FIGURE 82.3**). For example, should every teacher at a high school be expected to teach the same level and number of students and engage in the same number of extracurricular activities? Or should each job description be tailored to harness a specific person's unique strengths?

As noted earlier in the discussion of personnel psychologists, our temperament and our traits tend to follow us throughout our lives. Managers who excel spend less time trying to instill talents that are not there and more time developing and drawing out what is there. Kenneth Tucker (2002) has noted that effective managers

- start by helping people identify and measure their talents.
- match tasks to talents and then give people freedom to do what they do best.
- care how their people feel about their work.
- reinforce positive behaviors through recognition and reward.

Thus, rather than focusing on weaknesses and packing people off to training seminars to fix those problems, good managers focus training time on educating people about their strengths and building upon them (which means not promoting people into roles ill-suited to their strengths). In Gallup surveys, 77 percent of engaged workers, and only 23 percent of not-engaged workers, strongly agreed that "my supervisor focuses on my strengths or positive characteristics" (Krueger & Killham, 2005).

Celebrating engaged and productive employees in every organizational role builds upon a basic principle of operant conditioning (Modules 27 and 28): To teach a behavior, catch a person doing something right and reinforce it. It sounds simple, but many managers are like parents who, when a child brings home near-perfect scores, focus on the one low score in a troublesome biology class and ignore the rest. "Sixty-five percent of Americans received NO praise or recognition in the workplace last year," reported the Gallup Organization (2004).

Positive coaching Larry Brown has been an adviser to the youth sports organization Positive Coaching Alliance. He was observed during practices offering his players 4 to 5 positive comments for every negative comment (Insana, 2005). In 2004, he coached his underdog Detroit Pistons to the National Basketball Association championship.

SETTING SPECIFIC, CHALLENGING GOALS

In everyday life, our achievement goals sometimes involve approaching high levels of mastery or performance (such as mastering the material for this class and getting a high grade) and sometimes involve avoiding failure (Elliot & McGregor, 2001). In many situations, specific, challenging goals motivate achievement, especially when combined with progress reports (Johnson et al., 2006; Latham & Locke, 2007). Specific, measurable objectives, such as “finish gathering the history paper information by Friday,” serve to direct attention, promote effort, motivate persistence, and stimulate creative strategies.

When people state goals together with *subgoals* and *implementation intentions*—action plans that specify when, where, and how they will march toward achieving those goals—they become more focused in their work, and on-time completion becomes more likely (Burgess et al., 2004; Fishbach et al., 2006; Koestner et al., 2002). Through a task’s ups and downs, people best sustain their mood and motivation when they focus on immediate goals (such as daily study) rather than distant goals (such as a course grade). Better to have one’s nose to the grindstone than one’s eye on the ultimate prize (Houser-Marko & Sheldon, 2008). Thus, before beginning each new edition of this book, my editor, my associates, and I *manage by objectives*—we agree on target dates for the completion and editing of each unit draft. If we focus on achieving each of these short-term goals, the prize—an on-time book—takes care of itself. So, to motivate high productivity, effective leaders work with people to define explicit goals, subgoals, and implementation plans, and then provide feedback on progress.

task leadership goal-oriented leadership that sets standards, organizes work, and focuses attention on goals.

social leadership group-oriented leadership that builds teamwork, mediates conflict, and offers support.

“I’m the decider, and I decide what’s best.” –FORMER U.S. PRESIDENT GEORGE W. BUSH, 2006

CHOOSING AN APPROPRIATE LEADERSHIP STYLE

Leadership varies from a boss-focused directive style to a democratic style that empowers workers in setting goals and strategies. Which works best may depend on the situation and the leader. The best leadership style for leading a discussion may not be the best style for leading troops on a charge (Fiedler, 1981). Moreover, different leaders are suited to different styles. Some excel at **task leadership**—setting standards, organizing work, and focusing attention on goals. Being goal-oriented, task leaders are good at keeping a group centered on its mission. Typically, they have a directive style, which can work well if the leader is bright enough to give good orders (Fiedler, 1987).

Other managers excel at **social leadership**—explaining decisions, mediating conflicts, and building high-achieving teams (Evans & Dion, 1991). Social leaders often have a democratic style: They delegate authority and welcome the participation of team members. Many experiments show that social leadership is good for morale. Subordinates usually feel more satisfied

and motivated, and perform better, when they participate in decision making (Cawley et al., 1998; Pereira & Osburn, 2007). Moreover, groups solve problems with greater “collective intelligence” when group members are sensitive to one another and participate equally (Woolley et al., 2010).

Because effective leadership styles vary with the situation and the person, the once-popular *great person theory of leadership*—that all great leaders share certain traits—now seems overstated (Vroom & Jago, 2007; Wielkiewicz & Stelzner, 2005). The same coach may seem great or inferior depending on the strength of the team and its competition. But a leader’s personality does matter (Zaccaro, 2007). Effective leaders tend to be neither extremely assertive (impairing social relationships) or unassertive (limiting task leadership) (Ames, 2008). Effective leaders of laboratory groups, work teams, and large corporations also tend to exude *charisma* (House & Singh, 1987; Shamir et al., 1993). Their charisma blends a goal-based *vision*, clear *communication*, and optimism that *inspires* others to follow.

In one study of 50 Dutch companies, the firms with highest morale had chief executives who most inspired their colleagues “to transcend their own self-interests for the sake of the collective” (de Hoogh et al., 2004). *Transformational leadership* of this kind motivates others to identify with and commit themselves to the group’s mission. Transformational leaders, many of whom are natural extraverts, articulate high standards, inspire people to share their vision, and offer personal attention (Bono & Judge, 2004). The frequent result is more engaged, trusting, and effective workers (Turner et al., 2002). As leaders, women more than men tend to exhibit transformational leadership qualities. Alice Eagly (2007) believes this helps explain why companies with women in top management have tended to enjoy superior financial results, even after controlling for such variables as company size.

Peter Smith and Monir Tayeb (1989) compiled data from studies in India, Taiwan, and Iran indicating that effective managers—whether in coal mines, banks, or government offices—often exhibit a high degree of *both* task and social leadership. As achievement-minded people, effective managers certainly care about how well work is done, yet at the same time they are sensitive to their subordinates’ needs. In one national survey of U. S. workers, those in family-friendly organizations offering flexible-time hours reported feeling greater loyalty to their employers (Roehling et al., 2001). A work environment that satisfies one’s need to belong also energizes employees. Employees who enjoy high-quality colleague relationships also engage their work with more vigor (Carmeli et al., 2009). Gallup researchers have asked more than 15 million employees worldwide if they have a “best friend at work.” The 30 percent who do “are *seven times* as likely to be engaged in their jobs” as those who don’t, report Tom Rath and James Harter (2010).

Many successful businesses have also increased employee participation in making decisions, a management style common in Sweden and Japan and, increasingly, elsewhere (Naylor, 1990; Sundstrom et al., 1990). Although managers often think better of work they have directly supervised, studies reveal a *voice effect*: If given a chance to voice their opinion during a decision-making process, people will respond more positively to the decision (van den Bos & Spruijt, 2002). They will also feel more empowered, and likely, therefore, more creative (Hennessey & Amabile, 2010; Huang et al., 2010). And, as we noted earlier, positive, engaged employees are a mark of thriving organizations.

The ultimate in employee participation is the employee-owned company. One such company in my town, the Fleetwood Group, is a 165-employee manufacturer of educational furniture and wireless electronic clickers. When its founder gave 45 percent of the company to his employees, who later bought out other family stockholders, Fleetwood became one of the United States’ first companies with an employee stock ownership plan (ESOP). Today, every employee owns part of the company, and as a group they own 100 percent. The more years employees work, the more they own, yet no one owns more than 5 percent. Like every corporate president, Doug Ruch works for his stockholders—who also just happen to be his employees.

As a company that endorses faith-inspired “servant leadership” and “respect and care for each team member-owner,” Fleetwood is free to place people above profits. Thus, when orders

“Good leaders don’t ask more than their constituents can give, but they often ask—and get—more than their constituents intended to give or thought it was possible to give.” —JOHN W. GARDNER, *EXCELLENCE*, 1984

lagged during the recent recession, the employee-owners decided that job security meant more to them than profits. So the company paid otherwise idle workers to do community service—answering phones at nonprofit agencies, building Habitat for Humanity houses, and the like.

Fleetwood employees “act like they own the place,” notes Ruch. Employee ownership attracts and retains talented people, “drives dedication,” and gives Fleetwood “a sustainable competitive advantage,” he contends. With stock growth averaging 17 percent a year, Fleetwood was named the 2006 National ESOP of the year.

We have considered *personnel psychology* (the I/O subfield that focuses on employee selection, placement, appraisal, and development). And we have considered *organizational psychology* (the I/O subfield that focuses on worker satisfaction and productivity, and on organizational change). Finally, we turn to *human factors psychology*, which explores the human-machine interface.

Before You Move On

▶ ASK YOURSELF

Are you highly motivated, or not highly motivated, to achieve in school? How has this affected your academic success? How might you improve upon your own achievement levels?

▶ TEST YOURSELF

What are the two basic types of leadership, and how do the most effective managers employ these leadership strategies?

Answers to the Test Yourself questions can be found in Appendix E at the end of the book.

The Human Factor

82-5

How do human factors psychologists work to create user-friendly machines and work settings?

Designs sometimes neglect the human factor. Psychologist Donald Norman, an MIT alumnus with a Ph.D., bemoaned the complexity of assembling his new HDTV, related components, and seven remotes into a usable home theater system: “I was VP of Advanced Technology at Apple. I can program dozens of computers in dozens of languages. I understand television, really, I do. . . . It doesn’t matter: I am overwhelmed.”

How much easier life might be if engineers would routinely work with human factors psychologists to test their designs and instructions on real people. Human factors psychologists help to design appliances, machines, and work settings that fit our natural perceptions and inclinations. Bank automatic teller machines (ATMs) are internally more complex than remote controls ever were, yet, thanks to human factors psychologists working with engineers, ATMs are easier to operate. Digital recorders have solved the TV recording problem with a simple select-and-click menu system (“record that one”). Apple has similarly engineered easy usability with the iPhone and iPad.

Norman (2001) hosts a website (www.jnd.org) that illustrates good designs that fit people (**FIGURE 82.4**). Human factors psychologists also work at designing efficient environments. An ideal kitchen layout, researchers have found, stores needed items close to their usage point and near eye level. It locates work areas to enable doing tasks in order, such as with a refrigerator, stove, and sink in a triangle. It creates counters that enable hands to work at or slightly below elbow height (Boehm-Davis, 2005).

Understanding human factors can help prevent accidents. By studying the human factor in driving accidents, psychologists seek to devise ways to reduce the distractions, fatigue,

The Ride On Carry On foldable chair attachment, “designed by a flight attendant mom,” enables a small suitcase to double as a stroller.

The Oxo measuring cup allows the user to see the quantity from above.

The Chatsford Teapot comes with a built-in strainer.

Figure 82.4
Designing products that fit people Human factors psychologist Donald Norman offers these and other examples of effectively designed products.

and inattention that contribute to 1.3 million annual worldwide traffic fatalities (Lee, 2008). Two-thirds of commercial air accidents have been caused by human error (Nickerson, 1998). After beginning commercial flights in the 1960s, the Boeing 727 was involved in several landing accidents caused by pilot error. Psychologist Conrad Kraft (1978) noted a common setting for these accidents: All took place at night, and all involved landing short of the runway after crossing a dark stretch of water or unilluminated ground. Kraft reasoned that, beyond the runway, city lights would project a larger retinal image if on rising terrain. This would make the ground seem farther away than it was. By re-creating these conditions in flight simulations, Kraft discovered that pilots were deceived into thinking they were flying higher than their actual altitudes (**FIGURE 82.5**). Aided by Kraft’s finding, the airlines began requiring the co-pilot to monitor the altimeter—calling out altitudes during the descent—and the accidents diminished.

Later Boeing psychologists worked on other human factors problems (Murray, 1998): How should airlines best train and manage mechanics to reduce the maintenance errors that underlie about 50 percent of flight delays and 15 percent of accidents? What illumination and typeface would make on-screen flight data easiest to read? How could warning messages be most effectively worded—as an action statement (“Pull Up”) rather than a problem statement (“Ground Proximity”)?

Consider, finally, the available *assistive listening* technologies in various theaters, auditoriums, and places of worship. One technology, commonly available in the United States, requires a headset attached to a pocket-sized receiver that detects infrared or FM signals from the room’s sound system. The well-meaning people who design, purchase, and install these systems correctly understand that the technology puts sound directly into the user’s ears. Alas, few people with hearing loss undergo the hassle and embarrassment of locating, requesting, wearing, and returning a conspicuous headset. Most such units therefore sit in closets. Britain, the Scandinavian countries, and Australia have instead installed *loop systems* (see www.hearingloop.org) that broadcast customized sound directly through a person’s own hearing aid. When suitably equipped, a hearing aid can be transformed by a discrete touch of a switch into an in-the-ear loudspeaker. Offered convenient, inconspicuous, personalized sound, many more people elect to use assistive listening.

Designs that enable safe, easy, and effective interactions between people and technology often seem obvious after the fact. Why, then, aren’t they more common? Technology developers sometimes mistakenly assume that others share their expertise—that what’s clear to them will similarly be clear to others (Camerer et al., 1989; Nickerson, 1999). When people rap their knuckles on a table to convey a familiar tune (try this with a friend), they

Figure 82.5
The human factor in accidents Lacking distance cues when approaching a runway from over a dark surface, pilots simulating a night landing tended to fly too low. (From Kraft, 1978.)

The human factor in safe landings

Advanced cockpit design and rehearsed emergency procedures aided pilot Chesley “Sully” Sullenberger, a U.S. Air Force Academy graduate who studied psychology and human factors. In January 2009, Sullenberger’s instantaneous decisions safely guided his disabled airplane onto New York City’s Hudson River, where all 155 of the passengers and crew were safely evacuated.

AP Photo/Steven Day

often expect their listener to recognize it. But for the listener, this is a near-impossible task (Newton, 1991). When you know a thing, it’s hard to mentally simulate what it’s like not to know, and that is called the *curse of knowledge*.

The point to remember: Designers and engineers should consider human abilities and behaviors by designing things to fit people, user-testing their inventions before production and distribution, and being mindful of the curse of knowledge.

Before You Move On

▶ ASK YOURSELF

What situations have you experienced (using new technology, visiting new or remodeled building spaces, taking various modes of transportation), where the design did not work well? What situations have you experienced in which planners did a particularly good job matching machines and physical environments to our abilities and expectations?

▶ TEST YOURSELF

One of the ways human factors psychologists seek to reduce users’ frustration and to improve safety is by watching out for the curse of knowledge. What exactly is this tendency?

Answers to the Test Yourself questions can be found in Appendix E at the end of the book.

Module 82 Review

82-1

What is *flow*, and what are the three subfields of industrial-organizational psychology?

- *Flow* is a completely involved, focused state of consciousness with diminished awareness of self and time. It results from fully engaging one’s skills.
- I/O psychology’s three subfields are *personnel*, *organizational*, and *human factors* psychology.

82-2

How do personnel psychologists help organizations with employee selection, work placement, and performance appraisal?

- Personnel psychologists work with organizations to devise selection methods for new employees; recruit and evaluate applicants; design and evaluate training programs; identify people’s strengths; analyze job content; and appraise individual and organizational performance.
- Subjective interviews foster the interviewer illusion; *structured interviews* pinpoint job-relevant strengths and are better predictors of performance.
- Checklists, graphic rating scales, and behavior rating scales are useful performance appraisal methods.

82-3 What is *achievement motivation*? What is the role of organizational psychologists?

- *Achievement motivation* is the desire for significant accomplishment, for mastery of skills and ideas, for control, and for rapidly attaining a high standard.
- Organizational psychologists examine influences on worker satisfaction and productivity and facilitate organizational change. Employee satisfaction and engagement tend to correlate with organizational success.

82-4 What are some effective leadership techniques?

- Effective leaders harness job-relevant strengths; set specific challenging goals; and choose an appropriate leadership style. Leadership style may be goal-oriented (*task leadership*), or group-oriented (*social leadership*), or some combination of the two.

82-5 How do human factors psychologists work to create user-friendly machines and work settings?

- Human factors psychologists contribute to human safety and improved design by encouraging developers and designers to consider human perceptual abilities, to avoid the curse of knowledge, and to test users to reveal perception-based problems.

Multiple-Choice Questions

1. Which of the following is the best term or phrase for a completely involved state of consciousness with diminished awareness of self and time?
 - a. Flow
 - b. I/O psychology
 - c. Personnel psychology
 - d. Strengths
 - e. Achievement motivation
2. According to Angela Duckworth, passion and perseverance in the pursuit of long-term goals describes
 - a. wellness.
 - b. job analysis.
 - c. engagement.
 - d. grit.
 - e. task leadership.
3. The overall goal of 360-degree feedback is
 - a. self-rating.
 - b. achievement motivation.
 - c. performance appraisal.
 - d. selection.
 - e. performance.

Practice FRQ

1. Describe engaged, not engaged, and actively disengaged employees.

(3 points)

Module 83

Experienced Emotion: Anger and Happiness

Module Learning Objectives

- 83-1** Name some basic emotions, and describe two dimensions psychologists use to differentiate them.
- 83-2** Identify the causes and consequences of anger.
- 83-3** Identify the causes and consequences of happiness.

- 83-1** What are some basic emotions, and what two dimensions help differentiate them?

How many distinct emotions are there? Carroll Izard (1977) isolated 10 basic emotions (joy, interest-excitement, surprise, sadness, anger, disgust, contempt, fear, shame, and guilt), most of which are present in infancy (**FIGURE 83.1**). Jessica Tracy and Richard Robins (2004) believe that pride is also a distinct emotion, signaled by a small smile, head slightly tilted back, and an open posture. And Phillip Shaver and his colleagues (1996) believe that love, too, may be a basic emotion. But Izard has argued that other emotions are combinations of these 10, with love, for example, being a mixture of joy and interest-excitement.

Figure 83.1

Infants' naturally occurring emotions

To identify the emotions present from birth, Carroll Izard analyzed the facial expressions of infants.

(e) Surprise (brows raised, eyes widened, mouth rounded in oval shape)

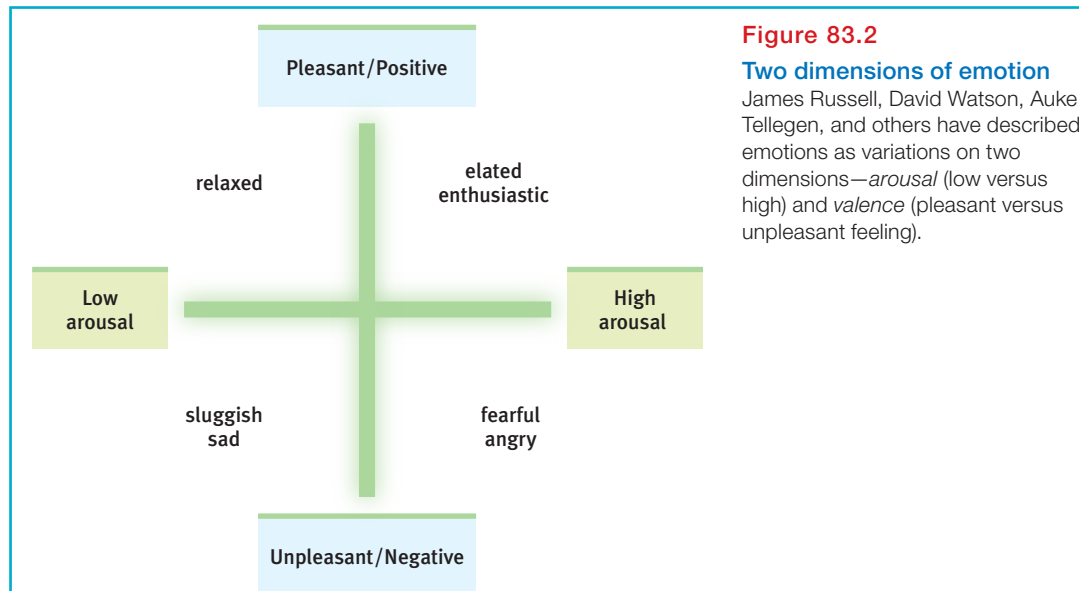

Arial Alvarez/Getty Images

(f) Sadness (brow's inner corners raised, mouth corners drawn down)

Vladimir Gocnik/Getty Images

(g) Fear (brows level, drawn in and up, eyelids lifted, mouth corners retracted)

The ingredients of emotion include not only physiology and expressive behavior but also our conscious experience. Across the world, people place emotional experience along the two dimensions illustrated in **FIGURE 83.2**—positive-versus-negative *valence*, and low-versus-high *arousal* (Russell et al., 1989, 1999a,b, 2009; Watson et al., 1999). Any emotion is some combination of feeling good versus bad, and of being aroused and energized or not. On the valence and arousal dimensions, *terrified* is more frightened (more unpleasant and aroused) than *afraid*, *enraged* is angrier than *angry*, *delighted* is happier than *happy*.

Let's take a closer look at anger and happiness. What functions do they serve? What influences our experience of each?

Anger

83-2 What are the causes and consequences of anger?

Anger, the sages have said, is “a short madness” (Horace, 65–8 B.C.E.) that “carries the mind away” (Virgil, 70–19 B.C.E.) and can be “many times more hurtful than the injury that caused it” (Thomas Fuller, 1654–1734). But they have also said that “noble anger” (William Shakespeare, 1564–1616) “makes any coward brave” (Cato, 234–149 B.C.E.) and “brings back . . . strength” (Virgil).

Facing a threat or challenge, fear triggers flight but anger triggers fight—each at times an adaptive behavior. What makes us angry? Sometimes anger is a response to someone's perceived misdeeds, especially when the person's act seems willful, unjustified, and avoidable (Averill, 1983). But small hassles and blameless annoyances—foul odors, high temperatures, dead cell phones, aches and pains—also have the power to make us angry (Berkowitz, 1990).

Anger can harm us: Chronic hostility is linked to heart disease. How, then, can we rid ourselves of our anger? In a Gallup teen survey, boys more than girls reported walking away from the situation or working it off with exercise; girls more often reported talking with a friend, listening to music, or writing (Ray, 2005). Popular books and articles sometimes advise that releasing angry feelings can be better than internalizing them. When irritated, should we lash out at the offender? Are advice columnists right in urging us to teach children to vent their anger? Are “recovery” therapists right in encouraging us to rage at our dead parents, imaginatively curse the boss, or confront our childhood abuser?

Blowing off steam with vuvuzelas

catharsis in psychology, the idea that “releasing” aggressive energy (through action or fantasy) relieves aggressive urges.

“Anger will never disappear so long as thoughts of resentment are cherished in the mind.”
- THE BUDDHA, 500 B.C.E.

SIX CHIX

Isabella Bannerman. Distributed by King Features Syndicate

The catharsis idea: Is it true?

Encouraging people to vent their rage is typical in individualist cultures, but it would seldom be heard in cultures where people’s identity is centered more on the group. People who keenly sense their *interdependence* see anger as a threat to group harmony (Markus & Kitayama, 1991). In Tahiti, for instance, people learn to be considerate and gentle. In Japan, from infancy on, angry expressions are less common than in American culture, where in recent politics, anger seems all the rage.

The Western vent-your-anger advice presumes that we can achieve emotional release, or **catharsis**, through aggressive action or fantasy. Experimenters report that *sometimes* when people retaliate against a provoker, they may indeed calm down. But this tends to be true only *if* they direct their counterattack toward the provoker, *if* their retaliation seems justifiable, and *if* their target is not intimidating (Geen & Quanty, 1977; Hokanson & Edelman, 1966). In short, expressing anger can be *temporarily* calming *if* it does not leave us feeling guilty or anxious. My daughter, a South African resident, experienced a temporary catharsis while cheering on her new country in a World Cup soccer match. “Every time I got angry at Uruguay, blowing that vuvuzela and joining the chorus of dissent released something in me.”

Despite the temporary afterglow, catharsis usually fails to cleanse one’s rage. More often, expressing anger breeds more anger. For one thing, it may provoke further retaliation, thus escalating a minor conflict into a major confrontation. For another, expressing anger can magnify anger. (Recall the behavior feedback research: *Acting* angry can make us *feel* angrier.) Anger’s backfire potential appeared in a study of 100 frustrated engineers and technicians just laid off by an aerospace company (Ebbesen et al., 1975). Researchers asked some workers questions that released hostility, such as, “What instances can you think of where the company has not been fair with you?” After expressing their anger, the workers later filled out a questionnaire that assessed their attitudes toward the company. Had the opportunity to “drain off” their hostility reduced it? Quite the contrary. These people expressed *more* hostility than those who had discussed neutral topics.

Other studies support this finding. In one, people who had been provoked were asked to wallop a punching bag while ruminating about the person who had angered them. Later, when given a chance for revenge, they became even more aggressive. “Venting to reduce anger is like using gasoline to put out a fire,” concluded the researcher, Brad Bushman (2002).

When anger fuels physically or verbally aggressive acts we later regret, it becomes maladaptive. Anger primes prejudice. After 9/11, Americans who responded with anger more than fear displayed intolerance for immigrants and Muslims (DeSteno et al., 2004; Skitka et al., 2004). Angry outbursts that temporarily calm us are dangerous in another way: They may be reinforcing and therefore habit forming. If stressed managers find they can drain off some of their tension by berating an employee, then the next time they feel irritated and tense they may be more likely to explode again. Think about it: The next time you are angry you are likely to repeat whatever relieved (and reinforced) your anger in the past.

What, then, is the best way to handle our anger? Experts offer two suggestions. First, wait. You can bring down the level of physiological arousal of anger by waiting. “It is true of the body as of arrows,” noted Carol Tavris (1982), “what goes up must come down. Any emotional arousal will simmer down if you just wait long enough.” Second, deal with anger in a way that involves neither being chronically angry over every little annoyance, nor sulking and rehearsing your grievances. Ruminating inwardly about the causes of your anger serves only to increase it (Rusting & Nolen-Hoeksema, 1998). Calm yourself by exercising, playing an instrument, or talking it through with a friend.

Anger is not always wrong. Used wisely, it can communicate strength and competence (Tiedens, 2001). It can benefit a relationship when it expresses a grievance in ways that promote reconciliation rather than retaliation. Controlled expressions of anger are more adaptive than either hostile outbursts or pent-up angry feelings. When James Averill (1983) asked people to recall or keep careful records of their experiences with anger, they often recalled reacting assertively rather than hurtfully. Their anger

frequently led them to talk things over with the offender, thereby lessening the aggravation. Civility means not only keeping silent about trivial irritations but also communicating important ones clearly and assertively. A nonaccusing statement of feeling—perhaps letting a sibling know that “I get irritated when you mess up my room while I’m away”—can help resolve the conflicts that cause anger.

What if someone’s behavior really hurts you, and you cannot resolve the conflict? Research commends the age-old response of forgiveness. Without letting the offender off the hook or inviting further harm, forgiveness releases anger and calms the body. To explore the bodily effects of forgiveness, Charlotte Witvliet and her co-researchers (2001) invited college students to recall an incident where someone had hurt them. As the students mentally rehearsed forgiveness, their negative feelings—and their perspiration, blood pressure, heart rate, and facial tension—all were lower than when they rehearsed their grudges.

Happiness

83-3 What are the causes and consequences of happiness?

Our state of happiness or unhappiness colors everything. Happy people perceive the world as safer and feel more confident. They make decisions and cooperate more easily, and are more tolerant. They rate job applicants more favorably, savor their positive past experiences without dwelling on the negative, and are more socially connected. They live healthier and more energized and satisfied lives (Briñol et al., 2007; Liberman et al., 2009; Mauss et al., 2011). When your mood is gloomy, life as a whole seems depressing and meaningless—and you think more skeptically and attend more critically to your surroundings. Let your mood brighten, and your thinking broadens and becomes more playful and creative (Baas et al., 2008; Forgas, 2008b; Fredrickson, 2006).

This helps explain why college students’ happiness helps predict their life course. In one study, women with natural, happy smiles in 1950s college yearbook photos were more likely to be happily married in middle age (Harker & Keltner, 2001). In another study, which surveyed thousands of U.S. college students in 1976 and restudied them at age 37, happy students had gone on to earn significantly more money than their less-happy-than-average peers (Diener et al., 2002). When we are happy, our relationships, self-image, and hopes for the future also seem more promising.

Moreover—and this is one of psychology’s most consistent findings—happiness doesn’t just feel good, it does good. In study after study, a mood-boosting experience (finding money, succeeding on a challenging task, recalling a happy event) has made people more likely to give money, pick up someone’s dropped papers, volunteer time, and do other good deeds. Psychologists call it the **feel-good, do-good phenomenon** (Salovey, 1990). (The reverse is also true: Doing good also promotes good feeling, a phenomenon harnessed by some happiness coaches as they assign people to perform a daily “random act of kindness” and to record the results.)

William James was writing about the importance of happiness (“the secret motive for all [we] do”) as early as 1902. With the twenty-first century rise of *positive psychology* (see Module 59) have come many studies of **subjective well-being**—our feelings of happiness (sometimes defined as a high ratio of positive to negative feelings) or sense of satisfaction with life.

The Short Life of Emotional Ups and Downs

Are some days of the week happier than others? In what is surely psychology’s biggest-ever data sample, social psychologist Adam Kramer (at my request and in cooperation with Facebook) did a naturalistic observation of emotion words in “billions” of status updates. After eliminating exceptional days, such as holidays, he tracked the frequency of positive and negative emotion words by day of the week. The most positive moods days? Friday and Saturday (**FIGURE 83.3** on the next page). For you, too?

feel-good, do-good phenomenon people’s tendency to be helpful when already in a good mood.

subjective well-being self-perceived happiness or satisfaction with life. Used along with measures of objective well-being (for example, physical and economic indicators) to evaluate people’s quality of life.

Figure 83.3
Using web science
to track happy days

Adam Kramer (personal correspondence, 2010) tracked positive and negative emotion words in many “billions” (the exact number is proprietary information) of status updates of U.S. Facebook users between September 7, 2007 and November 17, 2010.

Over the long run, our emotional ups and downs tend to balance out. This is true even over the course of the day (**FIGURE 83.4**). Positive emotion rises over the early to middle part of most days and then drops off (Kahneman et al., 2004; Watson, 2000). A stressful event—an argument, a sick child, a car problem—can trigger a bad mood. No surprise there. But by the next day, the gloom nearly always lifts (Affleck et al., 1994; Bolger et al., 1989; Stone & Neale, 1984). If anything, people tend to rebound from a bad day to a *better-than-usual* good mood the following day.

Even when negative events drag us down for longer periods, our bad mood usually ends. Those involved in romantic relationships expect their lives would be deflated by a breakup.

Actually, after a recovery period, their happiness level is about the same as for those who don't break up (Gilbert et al., 1998).

Grief over the loss of a loved one or anxiety after a severe trauma (such as child abuse, rape, or the terrors of war) can linger. But usually, even tragedy is not permanently depressing. People who become blind or paralyzed usually recover near-normal levels of day-to-day happiness. So do those who must go on kidney dialysis or have permanent colostomies (Gerhart et al., 1994; Riis et al., 2005; Smith et al., 2009). And in European studies, 8- to 12-year-olds with cerebral palsy experienced normal psychological well-being (Dickinson et al., 2007).

People mostly cope well with a permanent disability, although they may not rebound all the way back to their former emotions (Diener et al., 2006; Smith et al., 2009). A major disability leaves people less happy than average, yet much happier than able-bodied people with depression (Kübler et al., 2005; Lucas, 2007a,b; Oswald & Powdthavee, 2006; Schwartz & Estrin, 2004). “If you are a paraplegic,” explained Daniel Kahneman (2005), “you will gradually start thinking of other things, and the more time you spend thinking of other things the less miserable you are going to be.” Contrary to what many people believe, most patients “locked in” a motionless body do not indicate they want to die (Bruno et al., 2008, 2011; Smith & Delargy, 2005).

The surprising reality: *We overestimate the duration of our emotions and underestimate our resiliency and capacity to adapt.* (As one who inherited hearing loss with a trajectory toward that of my mother, who spent the last 13 years of her life completely deaf, I take heart from these findings.)

Human resilience Seven weeks after her 1994 wedding, Anna Putt of South Midlands, England, shown here with her husband, Des, suffered a brainstem stroke that left her “locked-in.” For months after, she recalled, “I was paralyzed from the neck down and was unable to communicate. These were VERY frightening times. But with encouragement from family, friends, faith, and medical staff, I tried to keep positive.” In the ensuing three years, she became able to “talk” (by nodding at letters), to steer an electric wheelchair with her head, and to use a computer (with head movements that guide a cursor). Despite her paralysis, she has reported that “I enjoy going out in the fresh air. My motto is ‘Don’t look back, move forward.’ God would not want me to stop trying and I have no intention of doing so. Life is what you make of it!”

“Weeping may tarry for the night,
but joy comes with the morning.”
- PSALM 30:5

Figure 83.4
Moods across the day

When psychologist David Watson (2000) sampled nearly 4500 mood reports from 150 people, he found this pattern of variation from the average levels of positive and negative emotions.

Wealth and Well-Being

“Do you think you would be happier if you made more money?” *Yes*, replied 73 percent of Americans in a 2006 Gallup poll. How important is “Being very well off financially?” *Very important*, say many entering U.S. collegians (**FIGURE 83.5**). Some 3 in 4 students rate their top two objectives (among 21) as being “very well off” and “raising a family,” and they grade them “extremely important” or “essential.”

Figure 83.5
The changing materialism of entering collegians Surveys of more than 200,000 entering U.S. collegians per year have revealed an increasing desire for wealth after 1970. (From *The American Freshman* surveys, UCLA, 1966 to 2012.)

And to a point, wealth does correlate with well-being. Consider:

- In most countries, and especially in poor countries, individuals with lots of money are typically happier than those who struggle to afford life’s basic needs (Diener & Biswas-Diener, 2009; Howell & Howell, 2008; Lucas & Schimmack, 2009). And, as we saw in Module 29, they often enjoy better health than those stressed by poverty and lack of control over their lives.
- People in rich countries also experience greater well-being than those in poor countries (Diener et al., 2009; Inglehart, 2008; **FIGURE 83.6**). The same is true for those in higher-income American states (Oswald & Wu, 2010).

So, it seems that money enough to buy your way out of hunger and hopelessness also buys some happiness. But once one has enough money for comfort and security, piling up more and more matters less and less. Ever more money does allow us to enjoy more things

Figure 83.6
Well-being across the planet The Gallup World Poll has surveyed nearly a half-million people across countries representing 99 percent of the human population. One question invited people to imagine a 10-step ladder, where 10 is “the best possible life for you” and 0 is “the worst possible life for you.” “On which step of the ladder would you say you personally feel you stand?” As you can see, people in the wealthier countries of North America, Western Europe, and Australia and New Zealand have tended to rate their lives higher. (Courtesy The Gallup Organization, 2011.)

"Money won't make you happy, Waldron. So instead of a raise, I'm giving a Prozac."

"Australians are three times richer than their parents and grandparents were in the 1950s, but they are not happier." - A MANIFESTO FOR WELL-BEING, 2005

and feel more control over our lives, but it does less to increase our *feelings* of happiness (Diener et al., 2009; Kahneman & Deaton, 2010). That's partly because of the *diminishing returns* phenomenon (familiar to economists as *diminishing marginal utility*). Experiencing luxury diminishes our savoring of life's simpler pleasures (Quoidbach et al., 2010). If you experience a friend's hot new smart-phone technology, your old phone—once so cool—may pale by comparison.

As Robert Cummins (2006) confirms with Australian data, the power of more money to increase happiness is significant at low incomes and diminishes as income rises. A \$1000 annual wage increase does a lot more for the average person in Malawi than for the average person in Switzerland. This implies, he adds, that raising low incomes will do more to increase happiness than raising high incomes.

And consider this: During the last half-century, the average U.S. citizen's buying power almost tripled. Did this greater wealth—enabling twice as many cars per person, not to mention iPods, laptops, and smart phones—also buy more happiness? As **FIGURE 83.7** shows, the average American, though certainly richer, is not a bit happier. In 1957, some 35 percent said they were "very happy," as did slightly fewer—32 percent—in 2008. Much the same has been true of Europe, Australia, and Japan, where increasing real incomes have *not* produced increasing happiness (Australian Unity, 2008; Diener & Biswas-Diener, 2002, 2009; Di Tella & MacCulloch, 2010). Ditto China, where living standards have risen but satisfaction has not (Brockmann et al., 2009). These findings lob a bombshell at modern materialism: *Economic growth in affluent countries has provided no apparent boost to morale or social well-being.*

Ironically, in every culture, those who strive hardest for wealth have tended to live with lower well-being (Ryan, 1999), especially when those hard-driving people were seeking money to prove themselves, gain power, or show off rather than support their families (Niemiec et al., 2009; Srivastava et al., 2001). Those who instead strive for intimacy, personal growth, and contribution to the community experience a higher quality of life (Kasser, 2002, 2011).

Figure 83.7

Does money buy happiness?

It surely helps us to avoid certain types of pain. Yet, though buying power has almost tripled since the 1950s, the average American's reported happiness has remained almost unchanged. (Happiness data from National Opinion Research Center surveys; income data from *Historical Statistics of the United States* and *Economic Indicators*.)

Two Psychological Phenomena: Adaptation and Comparison

Two psychological principles explain why, for those who are not poor, more money buys little more than a temporary surge of happiness and why our emotions seem attached to elastic bands that pull us back from highs or lows. In its own way, each principle suggests that happiness is relative.

HAPPINESS IS RELATIVE TO OUR OWN EXPERIENCE

The **adaptation-level phenomenon** describes our tendency to judge various stimuli in comparison with our past experiences. As psychologist Harry Helson (1898–1977) explained, we adjust our *neutral* levels—the points at which sounds seem neither loud nor soft, temperatures neither hot nor cold, events neither pleasant nor unpleasant—based on our experience. We then notice and react to variations up or down from these levels.

Thus, if our current condition—our income, academic average, or social prestige—improves, we feel an initial surge of pleasure, come to consider this new level normal, and require something even better to give us another surge of happiness. I can recall the childhood thrill of watching my family’s first 12-inch, black-and-white TV. Years later, after watching movies on a family member’s 60-inch high-definition flat screen, I adapted upward, and became unimpressed by my once wonderful 27-inch TV. Yesterday’s marvelous becomes today’s mundane.

HI & LOIS

So, could we ever create a permanent social paradise? Probably not (Campbell, 1975; Di Tella & MacCulloch, 2010). People who have experienced a recent windfall—from a lottery, an inheritance, or a surging economy—typically feel some elation (Diener & Oishi, 2000; Gardner & Oswald, 2007). So would you, if you woke up tomorrow to your Utopia—perhaps a world with no bills, no ills, perfect scores, someone who loves you unreservedly. But after a time, you would gradually recalibrate your adaptation level, and you would adjust your new neutral level to include these new experiences. Before long, you would again sometimes feel gratified (when events exceed your expectations) and sometimes feel deprived (when they fall below), and sometimes feel neutral. *The point to remember:* Feelings of satisfaction and dissatisfaction, success and failure are judgments we make based on our prior experience. Satisfaction, as Richard Ryan (1999) said, “has a short half life.” Ditto disappointment, which means that you may bounce back from a setback sooner than you expect.

HAPPINESS IS RELATIVE TO OTHERS’ SUCCESS

We are always comparing ourselves with others. And whether we feel good or bad depends on who those others are (Lyubomirsky, 2001). We are slow-witted or clumsy only when others are smarter or more agile. This sense that we are worse off than others with whom we compare ourselves is the concept of **relative deprivation**.

During World War II, U.S. Air Corps soldiers experienced a relatively rapid promotion rate. Nevertheless, many individual soldiers were frustrated about their own comparatively slow promotion rates (Merton & Kitt, 1950). Seeing so many others being promoted apparently inflated the soldiers’ expectations. Likewise, the economic surge that has made some urban Chinese newly affluent appears to have fueled among other Chinese a sense of relative deprivation (Burkholder, 2005a,b).

“No happiness lasts for long.” -
SENECA, *AGAMEMNON*, 60 C.E.

“Continued pleasures wear off Pleasure is always contingent upon change and disappears with continuous satisfaction.” - DUTCH PSYCHOLOGIST NICO FRIJDA (1988)

adaptation-level phenomenon
our tendency to form judgments (of sounds, of lights, of income) relative to a neutral level defined by our prior experience.

relative deprivation
the perception that we are worse off relative to those with whom we compare ourselves.

“I have a ‘fortune cookie maxim’ that I’m very proud of: Nothing in life is quite as important as you think it is while you are thinking about it. So, nothing will ever make you as happy as you think it will.” - NOBEL LAUREATE PSYCHOLOGIST DANIEL KAHNEMAN, GALLUP INTERVIEW, “WHAT WERE THEY THINKING?” 2005

FYI

The effect of comparison with others helps explain why students of a given level of academic ability tend to have a higher academic self-concept if they attend a school where most other students are not exceptionally able (Marsh & Parker, 1984). Imagine being near the top of your graduating class. You might feel inferior upon entering a college or university where all students were near the top of their class.

© The New Yorker Collection. 2001, Pat Byrnes from cartoonbank.com. All Rights Reserved

“Researchers say I’m not happier for being richer, but do you know how much researchers make?”

When expectations soar above attainments, the result is disappointment. Relative deprivation showed up again when Alex Rodriguez achieved a 10-year, \$275 million baseball contract. His deal surely made him temporarily happy, but it likely also diminished other star players’ satisfaction with their lesser, multimillion-dollar contracts. Satisfaction stems less from our income than our income rank (Boyce et al., 2010). Better to make \$50,000 when others make \$25,000 than to make \$100,000 when one’s friends, neighbors, and co-workers make \$200,000 (Solnick & Hemenway, 1998, 2009).

Such comparisons help us understand why the middle- and upper-income people in a given country, who can compare themselves with the relatively poor, tend to be more satisfied with life than are their less-fortunate compatriots. Nevertheless, once people reach a moderate income level, further increases buy little more happiness. Why? Because as people climb the ladder of success they mostly compare themselves with local peers who are at or above their current level (Gruder, 1977; Suls & Tesch, 1978; Zell & Alicke, 2010). “Beggars do not envy millionaires, though of course they will envy other beggars who are more successful,” noted Bertrand Russell (1930, p. 90). Thus, “Napoleon envied Caesar, Caesar envied Alexander, and Alexander, I daresay, envied Hercules, who never existed. You cannot, therefore, get away from envy by means of success alone, for there will always be in history or legend some person even more successful than you are” (pp. 68–69).

Just as comparing ourselves with those who are better off creates envy, so counting our blessings as we compare ourselves with those worse off boosts our contentment. In one study, University of Wisconsin-Milwaukee women considered others’ deprivation and suffering (Dermer et al., 1979). They viewed vivid depictions of how grim life was in Milwaukee in 1900. They imagined and then wrote about various personal tragedies, such as being burned and disfigured. Later, the women expressed greater satisfaction with their own lives. Similarly, when mildly depressed people have read about someone who was even more depressed, they felt somewhat better (Gibbons, 1986). “I cried because I had no shoes,” states a Persian saying, “until I met a man who had no feet.”

Predictors of Happiness

Happy people share many characteristics (**TABLE 83.1**). But why are some people normally so joyful and others so somber? Here, as in so many other areas, the answer is found in the interplay between nature and nurture.

Genes matter. In one study of 254 identical and fraternal twins, about 50 percent of the difference among people’s happiness ratings was heritable (Lykken & Tellegen, 1996). Other twin studies report similar or slightly less heritability (Bartels & Boomsma, 2009; Lucas, 2008; Nes et al., 2010). Identical twins raised apart are often similarly happy.

Table 83.1 Happiness Is . . .

Researchers Have Found That Happy People Tend to	However, Happiness Seems Not Much Related to Other Factors, Such as
Have high self-esteem (in individualist countries).	Age.
Be optimistic, outgoing, and agreeable.	Gender (women are more often depressed, but also more often joyful).
Have close friendships or a satisfying marriage.	Parenthood (having children or not).
Have work and leisure that engage their skills.	Physical attractiveness.
Have an active religious faith.	
Sleep well and exercise.	

Sources: Summarized from DeNeve & Cooper (1998), Diener et al. (2003), Headey et al. (2010), Lucas et al. (2004), Myers (1993, 2000), Myers & Diener (1995, 1996), and Steel et al. (2008). Veenhoven (2009) offers a database of 11,000+ correlates of happiness at www.worlddatabaseofhappiness.eur.nl.

But our personal history and our culture matter, too. On the personal level, as we have seen, our emotions tend to balance around a level defined by our experience. On the cultural level, groups vary in the traits they value. Self-esteem and achievement matter more to Westerners, who value individualism. Social acceptance and harmony matter more to those in communal cultures such as Japan that stress family and community (Diener et al., 2003; Uchida & Kitayama, 2009).

Depending on our genes, our outlook, and our recent experiences, our happiness seems to fluctuate around our “happiness set point,” which disposes some people to be ever upbeat and others more negative. Even so, after following thousands of lives over two decades, researchers have determined that our satisfaction with life is not fixed (Lucas & Donnellan, 2007). Happiness rises and falls, and can be influenced by factors that are under our control. A striking example: In a long-term German study, married partners were as similarly satisfied with their lives as were identical twins (Schimmack & Lucas, 2007). Genes matter. But as this study hints, relationship quality matters, too. (For research-based hints on enhancing your own happiness, see *Close-up: Want to Be Happier?*)

FYI

Studies of chimpanzees in zoos reveal that happiness in chimpanzees, as rated by 200 employees, is also genetically influenced (Weiss et al., 2000, 2002).

Close-up**Want to Be Happier?**

Your happiness, like your cholesterol level, is genetically influenced. Yet as cholesterol is also influenced by diet and exercise, so happiness is partly under your control (Nes, 2010; Sin & Lyubomirsky, 2009). Here are some research-based suggestions for improving your mood and increasing your satisfaction with life.

Realize that enduring happiness may not come from financial success. We adapt to change by adjusting our expectations. Neither wealth, nor any other circumstance we long for, will guarantee happiness.

Take control of your time. Happy people feel in control of their lives. To master your use of time, set goals and divide them into daily aims. This may be frustrating at first because we all tend to overestimate how much we will accomplish in any given day. The good news is that we generally *underestimate* how much we can accomplish in a year, given just a little progress every day.

Act happy. As you saw in Module 42, people who were manipulated into a smiling expression felt better. So put on a happy face. Talk as *if* you feel positive self-esteem, are optimistic, and are outgoing. We can often act our way into a happier state of mind.

Seek work and leisure that engage your skills. Happy people often are in a zone called *flow*—absorbed in tasks that challenge but don’t overwhelm them. Passive forms of leisure (watching TV) often provide less flow experience than socializing, hiking, or creative work. Money also buys more happiness when spent on experiences that you can look forward to, enjoy, and remember than when spent on material stuff (Carter & Gilovich, 2010). As pundit Art Buchwald said, “The best things in life aren’t things.”

Join the “movement” movement. Aerobic exercise can relieve mild depression and anxiety as it promotes health and

RubberBall Selects/Alamy

energy. Sound minds reside in sound bodies. Off your duffs, couch potatoes!

Give your body the sleep it wants.

Happy people live active lives yet reserve time for renewing sleep and solitude. Many people suffer from sleep debt, with resulting fatigue, diminished alertness, and gloomy moods.

Give priority to close relationships. Intimate friendships can help you weather difficult times. Confiding is good for soul and body. Compared with unhappy people, happy people engage in less superficial small talk and more meaningful conversations (Mehl et al., 2010). So resolve to nurture your closest relationships by *not* taking your loved ones for granted. This means displaying to them the sort of kindness you display to others, affirming them, playing together, and sharing together.

Focus beyond self. Reach out to those in need. Happiness increases helpfulness (those who feel good do good). But doing good also makes one feel good.

Count your blessings and record your gratitude. Keeping a gratitude journal heightens well-being (Emmons, 2007; Seligman et al., 2005). Try pausing each day to savor good moments, and to record positive events and why they occurred. Express your gratitude to others.

Nurture your spiritual self. For many people, faith provides a support community, a reason to focus beyond self, and a sense of purpose and hope. That helps explain why people active in faith communities report greater-than-average happiness and often cope well with crisis.

Digested from David G. Myers, *The Pursuit of Happiness* (Harper).

Figure 83.8

Declining well-being in Egypt and Tunisia prior to popular revolts

In Gallup surveys, the percentage of people who were “thriving” (rating their life satisfaction 7 or higher and projecting their next five years at 8 or higher on a 10-step scale) declined in advance of 2011 demonstrations that led to a change of government (Clifton & Morales, 2011).

If we can enhance our happiness on an individual level, could we use happiness research to refocus our national priorities more on advancing psychological well-being? Many psychologists believe we could. Diener (2006, 2009), (2006), supported by 52 colleagues, has proposed ways in which nations might measure national well-being. “Policymakers should be interested in subjective well-being not only because of its inherent value to citizens, but also because individuals’ subjective well-being can have positive spillover benefits for the society as a whole.” Happiness research offers new ways to assess the impacts of various public policies, argue Diener and his colleagues. Happy societies are not only prosperous, but also places where people trust one another, feel free, and enjoy close relationships (Oishi & Schimmack, 2010). Thus, when debating the minimum wage, economic inequality, tax rates, divorce laws, health care, and neighborhood planning, people’s psychological well-being should be a prime consideration—a point now affirmed by the Canadian, French, German, and British governments, which have added well-being measures to their national agendas (Cohen, 2011; Gertner, 2010; Stiglitz, 2009). The predictive power of national well-being assessments was apparent in 2011, as the governments of Egypt and Tunisia first succumbed to popular uprisings in the aftermath of declining life satisfaction (**FIGURE 83.8**).

Before You Move On

▶ ASK YOURSELF

If we learn our emotional responses, we may be able to learn new responses to replace old ones. Would you like to change any of your emotional responses? Do you feel you are too easily provoked to anger, for instance? How might you go about changing your behavior or your thinking in order to change your emotional reactions?

▶ TEST YOURSELF

What things do (and do not) predict self-reported happiness?

Answers to the Test Yourself questions can be found in Appendix E at the end of the book.

Module 83 Review

83-1

What are some basic emotions, and what two dimensions help differentiate them?

- Caroll Izard’s 10 basic emotions are joy, interest-excitement, surprise, sadness, anger, disgust, contempt, fear, shame, and guilt.
- The two dimensions of emotion are positive-versus-negative valence, and low-versus-high arousal.

83-2

What are the causes and consequences of anger?

- Anger is most often evoked by misdeeds that we interpret as willful, unjustified, and avoidable. But smaller frustrations and blameless annoyances can also trigger anger.
- Emotional *catharsis* may be temporarily calming, but in the long run it does not reduce anger. Rehearsing anger can make us more angry.
- Controlled assertions of feelings may resolve conflicts, and forgiveness may rid us of angry feelings.

83-3**What are the causes and consequences of happiness?**

- A good mood brightens people's perceptions of the world and makes them more willing to help others (the *feel-good, do-good phenomenon*).
- The moods triggered by good or bad events seldom last beyond that day. Even significant good events, such as sudden wealth, seldom increase happiness for long.
- Happiness is relative to our own experiences (the *adaptation-level phenomenon*) and to others' success (the *relative deprivation principle*).
- Some individuals seem genetically predisposed to be happier than others. Cultures, which vary in the traits they value and the behaviors they expect and reward, also influence personal levels of happiness.

Multiple-Choice Questions

1. The idea that releasing aggressive energy will relieve aggressive urges is called
 - a. subjective well-being.
 - b. the adaptation-level phenomenon.
 - c. resilience.
 - d. catharsis.
 - e. valence.
2. Which of the following do psychologists say is the best way to handle anger?
 - a. Venting with a friend about the source of your anger
 - b. Dealing with the situation right away so the anger does not build
 - c. Playing violent video games so the anger can subside
 - d. Waiting for the arousal to subside
 - e. Keeping the source of anger to yourself so it cannot cause additional problems
3. Which of the following is an example of the feel-good, do-good phenomenon?
 - a. Anagha tries to keep her 2-year-old son from becoming upset for any reason.
 - b. Niko is praised by his teacher and later volunteers to help his mother clean the garage.
 - c. Carrsan felt satisfied after helping the ecology club pick up trash around the school.
 - d. Maggie's parents doubled her allowance when she was nice to her sister all day.
 - e. Rowen was glad to finally be over the flu so he could return to his volunteer work.
4. Which of the following accurately represents the relationship between happiness and wealth?
 - a. Rapidly increasing wealth is associated with a slight decrease in happiness because of relative deprivation.
 - b. Increased wealth increases happiness equally for almost everybody.
 - c. There is no relationship between wealth and happiness.
 - d. Gradually increasing wealth is associated with a slight decrease in happiness because of the adaptation-level phenomenon.
 - e. Increased wealth increases happiness for people who don't have enough money to meet their basic needs.

Practice FRQ

1. Describe two factors that are associated with happiness and two that are not.

(4 points)

Module 84

Human Flourishing

Module Learning Objectives

- 84-1** Discuss the links among basic outlook on life, social support, stress, and health.
- 84-2** Discuss the advantages of aerobic exercise as a way to manage stress and improve well-being.
- 84-3** Describe how relaxation and meditation might influence stress and health.
- 84-4** Define *complementary and alternative medicine*, and explain how it is best assessed through scientific research.
- 84-5** Describe what is meant by the faith factor, and offer some possible explanations for the link between religious involvement and longevity.

health psychology a subfield of psychology that provides psychology's contribution to behavioral medicine.

Promoting Health

Promoting health begins with implementing strategies that prevent illness and enhance wellness. Traditionally, people have thought about their health only when something goes wrong—visiting a physician for diagnosis and treatment. That, say **health psychologists**, is like ignoring a car's maintenance and going to a mechanic only when the car breaks down. Health maintenance includes alleviating stress, preventing illness, and promoting well-being.

Optimism and Health

- 84-1** What are the links among basic outlook on life, social support, stress, and health?

One aspect of our health and our coping with stress is our outlook—what we expect from the world. *Pessimists* expect things to go badly. *Optimists* agree with statements such as, “In uncertain times, I usually expect the best.” People with an optimistic outlook expect to have more control, to cope better with stressful events, and to enjoy better health (Aspinwall & Tedeschi, 2010; Carver et al., 2010; Rasmussen et al., 2009). During the last month of a semester, students previously identified as optimistic reported less fatigue and fewer coughs, aches, and pains. And during the stressful first few weeks of law school, those who were optimistic (“It’s unlikely that I will fail”) enjoyed better moods and stronger immune systems (Seegerstrom et al., 1998). Optimists also respond to stress with smaller increases in blood pressure, and they recover more quickly from heart bypass surgery.

Consider the consistency and startling magnitude of the optimism and positive emotions factor in several other studies:

- One research team followed 941 Dutch people, ages 65 to 85, for nearly a decade (Giltay et al., 2004, 2007). Among those in the lowest optimism quartile, 57 percent died, as did only 30 percent of the top optimism quartile.
- When Finnish researchers followed 2428 men for up to a decade, the number of deaths among those with a bleak, hopeless outlook was more than double that found among their optimistic counterparts (Everson et al., 1996). American researchers found the same when following 4256 Vietnam-era veterans (Phillips et al., 2009).
- A now-famous study followed up on 180 Catholic nuns who had written brief autobiographies at about 22 years of age and had thereafter lived similar lifestyles. Those who had expressed happiness, love, and other positive feelings in their autobiographies lived an average 7 years longer than their more dour counterparts (Danner et al., 2001). By age 80, some 54 percent of those expressing few positive emotions had died, as had only 24 percent of the most positive spirited.

The oldest Holocaust survivor explaining her 107 years: “In a word: optimism. I look at the good. When you are relaxed, your body is always relaxed.” - Alice Herz-Sommer, 2010

Social Support

Social support—feeling liked and encouraged by intimate friends and family—promotes both happiness and health. In massive investigations, some following thousands of people for several years, close relationships have predicted health. People are less likely to die early if supported by close relationships (Uchino, 2009). When Brigham Young University researchers combined data from 148 studies totaling more than 300,000 people worldwide, they confirmed a striking effect of social support (Holt-Lunstad et al., 2010). During the studies, those with ample social connections had survival rates about 50 percent greater than those with meager connections. The impact of meager connections appeared roughly equal to the effect of smoking 15 cigarettes a day or having alcohol use disorder, and double the effect of not exercising or being obese. People aren’t the only creatures to benefit from friends. Among baboons, strong social bonds with relatives and friends similarly predicts longevity (Silk et al., 2010).

People need people. Some fill this need by connecting with friends, family, co-workers, members of a faith community, or other support groups. Others connect in positive, happy, supportive marriages. People in low-conflict marriages live longer, healthier lives than the unmarried (De Vogli et al., 2007; Kaplan & Kronick, 2006; Sbarra, 2009). This correlation holds regardless of age, sex, race, and income (National Center for Health Statistics, 2004). One seven-decade-long study found that at age 50, healthy aging is better predicted by a good marriage than by a low cholesterol level (Vaillant, 2002). But the married versus never-married health gap has shrunk (Liu, 2009).

How can we explain the link between social support and health? Is it because middle-aged and older adults who live alone are more likely to smoke, be obese, and have high cholesterol—and therefore to have a doubled risk of heart attacks (Nielsen et al., 2006)? Or because healthy people are more supportive and marriage-prone? Possibly. But research indicates some other possibilities.

Social support calms us and reduces blood pressure and stress hormones. More than 50 studies support this finding (Graham et al., 2006; Uchino et al., 1996, 1999). To see if social support might calm people’s response to threats, one research team subjected happily married women, while lying in an fMRI machine, to the threat of electric shock to an ankle (Coan et al., 2006). During the experiment, some women held their husband’s hand. Others held the hand of an unknown person or no hand at all. While awaiting the occasional

Laughter among friends is good medicine

Laughter arouses us, massages muscles, and then leaves us feeling relaxed (Robinson, 1983). Humor (though not hostile sarcasm) may defuse stress, ease pain, and strengthen immune activity (Ayan, 2009; Berk et al., 2001; Kimata, 2001). People who laugh a lot also tend to have lower rates of heart disease (Clark et al., 2001).

Mark Andersen/Getty Images

"Woe to one who is alone and falls and does not have another to help." - Ecclesiastes 4:10

shocks, women holding their husband's hand showed less activity in threat-responsive areas. This soothing benefit was greatest for those reporting the highest-quality marriages. Supportive family and friends—human and nonhuman—help buffer threats. After stressful events, Medicare patients who have a dog or other companionable pet are less likely to visit their doctor (Siegel, 1990). (See Close-up: Pets Are Friends, Too.)

Social support fosters stronger immune functioning. Volunteers in studies of resistance to cold viruses showed this effect (Cohen et al., 1997, 2004). In those studies, healthy volunteers inhaled nasal drops laden with a cold virus and were quarantined and observed for five days. (In these experiments, more than 600 volunteers received \$800 each to endure this experience.) Age, race, sex, smoking, and other health habits being equal, those with the most social ties were least likely to catch a cold. If they did catch one, they produced less mucus. More sociability meant less susceptibility. The cold fact is that the effect of social ties is nothing to sneeze at!

Close relationships give us an opportunity for "open heart therapy," a chance to confide painful feelings (Frattaroli, 2006). Talking about a stressful event can temporarily arouse us, but in the long run it calms us by calming limbic system activity (Lieberman et al., 2007; Mendolia & Kleck, 1993). In one study, 33 Holocaust survivors spent two hours recalling their experiences, many in intimate detail never before disclosed (Pennebaker et al., 1989). In the weeks following, most watched a tape of their recollections and showed it to family and friends. Those who were most self-disclosing had the most improved health 14 months later. Confiding is good for the body and the soul. In another study of surviving spouses of people who had committed suicide or died in car accidents, those who bore their grief alone had more health problems than those who could express it openly (Pennebaker & O'Heeron, 1984).

Close-up

Pets Are Friends, Too

Have you ever wished for a friend who would love you just as you are? One who would never judge you? Who would be there for you, no matter your mood? For many tens of millions of people that friend exists, and it is a loyal dog or a friendly cat.

Many people describe their pet as a cherished family member who helps them feel calm, happy, and valued. Can pets also help people handle stress? If so, might pets have healing power? The evidence is, as yet, mixed and meager (Herzog, 2010). But Deborah Wells (2009) and Karen Allen (2003) have reported that pets have sometimes been found to increase the odds of survival after a heart attack, to relieve depression among AIDS patients, and to lower the level of blood pressure and blood lipids that contribute to cardiovascular risk. As nursing pioneer Florence Nightingale (1860) foresaw, "A small pet animal is often an excellent companion for the sick." In one study, women's blood pressure rose as they struggled with challenging math problems in the presence of a best friend or even a spouse, but much less so when accompanied by their dog (Allen, 2003).

So, would pets be good medicine for people who do not have pets? To find out, Allen experimented. The participants

were a group of stockbrokers who lived alone, described their work as stressful, and had high blood pressure. She randomly selected half to adopt an animal shelter cat or dog. When later facing stress, all participants experienced higher blood pressure. But among the new pet owners, the increase was less than half as high as the increase in the no-pet group. The effect was greatest for pet owners with few social contacts or friends. Allen's conclusion: For lowering blood pressure, pets are no substitute for effective drugs and exercise. But for those who enjoy animals, and especially for those who live alone, they are a healthy pleasure.

Suppressing emotions can be detrimental to physical health. When health psychologist James Pennebaker (1985) surveyed more than 700 undergraduate women, about 1 in 12 of them reported a traumatic sexual experience in childhood. The sexually abused women—especially those who had kept their secret to themselves—reported more headaches and stomach ailments than did other women who had experienced nonsexual traumas, such as parental death or divorce. Another study, of 437 Australian ambulance drivers, confirmed the ill effects of suppressing one’s emotions after witnessing traumas (Wastell, 2002).

Even writing about personal traumas in a diary can help (Burton & King, 2008; Hemenover, 2003; Lyubomirsky et al., 2006). In one experiment, volunteers who did so had fewer health problems during the ensuing four to six months (Pennebaker, 1990). As one participant explained, “Although I have not talked with anyone about what I wrote, I was finally able to deal with it, work through the pain instead of trying to block it out. Now it doesn’t hurt to think about it.”

If we are aiming to exercise more, drink less, quit smoking, or be a healthy weight, our social ties can tug us away from or toward our goal. Studies of networks of thousands of people followed over years suggest that clusters of friends may “infect” one another with either bad health practices or good behaviors (Christakis & Fowler, 2009). Obesity, for example, spreads within networks in ways that seem not merely to reflect people’s seeking out similar others.

Reducing Stress

Having a sense of control (Module 29), developing more optimistic thinking, and building social support can help us *experience* less stress and thus improve our health. Moreover, these factors interrelate: People who are upbeat about themselves and their future tend also to enjoy health-promoting social ties (Stinson et al., 2008). But sometimes we cannot alleviate stress and simply need to *manage* our stress. Aerobic exercise, relaxation, meditation, and spiritual communities may help us gather inner strength and lessen stress effects.

Aerobic Exercise

84-2

How effective is aerobic exercise as a way to manage stress and improve well-being?

Aerobic exercise is sustained, oxygen-consuming exercise—such as jogging, swimming, or biking—that increases heart and lung fitness. It’s hard to find bad things to say about exercise. By one estimate, moderate exercise adds not only to your quantity of life—two additional years, on average—but also to your quality of life, with more energy and better mood (Seligman, 1994).

Exercise helps fight heart disease by strengthening the heart, increasing bloodflow, keeping blood vessels open, and lowering both blood pressure and the blood pressure reaction to stress (Ford, 2002; Manson, 2002). Compared with inactive adults, people who exercise suffer half as many heart attacks (Powell et al., 1987; Visich & Fletcher, 2009). Exercise makes the muscles hungry for the fats that, if not used by the muscles, contribute to clogged arteries (Barinaga, 1997). In one 20-year study of adult Finnish twins, other things being equal, daily conditioning exercise reduced death risk by 43 percent (Kujala et al., 1998). Regular exercise in later life also predicts better cognitive functioning and reduced risk of neurocognitive disorder and Alzheimer’s disease (Kramer & Erickson, 2007).

The genes passed down to us from our distant ancestors were those that enabled the physical activity essential to hunting, foraging, and farming. In muscle cells, those genes, when activated by exercise, respond by producing proteins. In the modern inactive person, these genes

aerobic exercise sustained exercise that increases heart and lung fitness; may also alleviate depression and anxiety.

“Is there anyone here who specializes in stress management?”

Figure 84.1

Aerobic exercise and depression

Mildly depressed college women who participated in an aerobic exercise program showed markedly reduced depression, compared with those who did relaxation exercises or received no treatment. (From McCann & Holmes, 1984.)

Paik Photography/Alamy

produce lower quantities of proteins and leave us susceptible to more than 20 chronic diseases, such as type-2 diabetes, cardiovascular disease, Alzheimer's disease, and cancer (Booth & Neuffer, 2005). Inactivity is thus potentially toxic.

Does exercise also boost the spirit? Many studies reveal that aerobic exercise can reduce stress, depression, and anxiety. Americans, Canadians, and Britons who do aerobic exercise at least three times a week manage stress better, exhibit more self-confidence, feel more vigor, and feel less depressed and fatigued than their inactive peers (McMurray, 2004; Mead et al., 2010; Puetz et al., 2006). And in a 21-country survey of university students, physical exercise was a "strong" and consistent predictor of life satisfaction (Grant et al., 2009).

But we could state this observation another way: Stressed and depressed people

exercise less. These findings are correlations, and cause and effect are unclear. To sort out cause and effect, researchers experiment. They randomly assign stressed, depressed, or anxious people either to an aerobic exercise group or to a control group. One classic experiment randomly assigned mildly depressed female college students to three groups. One-third participated in a program of aerobic exercise. Another third took part in a program of relaxation exercises. The remaining third (the control group) formed a no-treatment group (McCann & Holmes, 1984). As **FIGURE 84.1** shows, 10 weeks later, the women in the aerobic exercise program reported the greatest decrease in depression. Many had, quite literally, run away from their troubles. Dozens of other experiments confirm that exercise prevents or reduces depression and anxiety (Conn, 2010; Rethorst et al., 2009; Windle et al., 2010). Vigorous exercise provides a substantial and immediate mood boost (Watson, 2000).

Even a 10-minute walk stimulates two hours of increased well-being by raising energy levels and lowering tension (Thayer, 1987, 1993).

Some studies indicate that not only is exercise as effective as drugs, it better prevents symptom recurrence (Babyak et al., 2000; Salmon, 2001). In exploring *why* aerobic exercise alleviates negative emotions, researchers have found that exercise in some ways works like an antidepressant drug. Exercise increases arousal, thus counteracting depression's low-arousal state. It often leads to muscle relaxation and sounder sleep. It also orders up mood-boosting chemicals from our body's internal pharmacy—neurotransmitters such as norepinephrine, serotonin, and the endorphins (Jacobs, 1994; Salmon, 2001). And it may foster *neurogenesis*. In mice, exercise causes the brain to produce a molecule that acts as a natural antidepressant, by stimulating the production of new, stress-resistant neurons (Hunsberger et al., 2007; Reynolds, 2009; van Praag, 2009). On a simpler level, the sense of accomplishment and improved physique and body image that often accompany a successful exercise

The mood boost When one's energy or spirits are sagging, few things reboot the day better than exercising (as I can confirm from my daily noontime basketball). Aerobic exercise appears to counteract depression partly by increasing arousal (replacing depression's low-arousal state) and by doing naturally what antidepressants do—increasing the brain's serotonin activity.

Kathryn Brownson

routine may enhance one's self-image, leading to a better emotional state. Exercise (at least a half-hour on five or more days of the week) is like a drug that prevents and treats disease, increases energy, calms anxiety, and boosts mood—a drug we would all take, if available. Yet few people (only 1 in 4 in the United States) take advantage of it (Mendes, 2010).

RELAXATION AND MEDITATION

84-3 In what ways might relaxation and meditation influence stress and health?

In the late 1960s, some respected psychologists wondered if we could learn to counteract our stress responses by altering our thinking and lifestyle. As we learned in Module 28, they began experimenting with *biofeedback*, a system of recording, amplifying, and feeding back information about subtle physiological responses, many controlled by the autonomic nervous system. However, a decade of study revealed only limited effectiveness, with biofeedback working best on tension headaches (Miller, 1985; NIH, 1995).

Simple methods of relaxation, which require no expensive equipment, produce many of the results biofeedback once promised. Figure 84.1 pointed out that aerobic exercise reduces depression. But did you notice in that figure that depression also decreased among women in the relaxation treatment group? More than 60 studies have found that relaxation procedures can also help alleviate headaches, hypertension, anxiety, and insomnia (Nestoriuc et al., 2008; Stetter & Kupper, 2002). Such findings would not surprise Meyer Friedman and his colleagues (whose classic studies of stress and heart disease were discussed in Module 44). They tested relaxation in a program designed to help hard-driving Type A heart attack survivors reduce their risk of future attacks, by randomly assigning hundreds of middle-aged men to one of two groups. The first group received standard advice from cardiologists about medications, diet, and exercise habits. The second group received similar advice, but they also were taught ways of modifying their lifestyles. They learned to slow down and relax by walking, talking, and eating more slowly. They learned to smile at others and laugh at themselves. They learned to admit their mistakes; to take time to enjoy life; and to renew their religious faith. The training paid off (**FIGURE 84.2**). During the next three years, the group that learned to modify their lifestyle had half as many repeat heart attacks as did the first group. This, wrote the exuberant Friedman, was an unprecedented, spectacular reduction in heart attack recurrence. A smaller-scale British study similarly divided heart-attack-prone people into control and lifestyle modification groups (Eysenck & Grossarth-Maticek, 1991). During the next 13 years, that study also showed a 50 percent reduction in death rate among people trained to alter their thinking and lifestyle. After suffering a heart attack at age 55, Friedman started taking his own behavioral medicine—and lived to age 90 (Wargo, 2007).

Figure 84.2
Recurrent heart attacks and lifestyle modification The San Francisco Recurrent Coronary Prevention Project offered counseling from a cardiologist to survivors of heart attacks. Those who were also guided in modifying their Type A lifestyle suffered fewer repeat heart attacks. (From Friedman & Ulmer, 1984.)

FYI

Meditation is a modern phenomenon with a long history: “Sit down alone and in silence. Lower your head, shut your eyes, breathe out gently, and imagine yourself looking into your own heart. . . . As you breathe out, say ‘Lord Jesus Christ, have mercy on me.’ . . . Try to put all other thoughts aside. Be calm, be patient, and repeat the process very frequently” (Gregory of Sinai, died 1346).

Blend Images/Alamy

**FYI**

And then there are the mystics who seek to use the mind’s power to enable novocaine-free cavity repair. Their aim: transcendental medication.

Cardiologist Herbert Benson (1996) became intrigued with reports that experienced meditators could lower their blood pressure, heart rate, and oxygen consumption and raise their fingertip temperature. His research led him to what he now calls the *relaxation response*, a state of calm marked by relaxed muscles, slowed breathing and heart rate, and decreased blood pressure. According to Benson, relaxation practiced once or twice daily has lasting stress-reducing benefits.

To experience the relaxation response, the Benson-Henry Institute for Mind Body Medicine recommends these steps: Sit quietly in a comfortable position. Close your eyes. Relax your muscles, starting with your feet, then your calves, and upward through your thighs, shoulders, neck, and head. Breathe slowly. As you exhale each breath, repeat a focus word, phrase, or prayer—something drawn from your own belief system. When other thoughts intrude, don’t worry. Just return to your repetition and continue for 10 to 20 minutes. When finished, sit quietly for another minute or two, then open your eyes and sit for a few more moments.

Tibetan Buddhists deep in meditation and Franciscan nuns deep in centering prayer report a diminished sense of self, space, and time. Brain scans reveal the neural footprints of such spiritual feelings during these mystical experiences: A part of the parietal lobe that tracks our location in space is less active than usual, and a frontal lobe area involved in focused attention is more active (Cahn & Polich, 2006; Newberg & D’Aquili, 2001). Another difference appears in the brain’s left frontal lobe. In Buddhist monks who are experienced in meditation, this area displays elevated levels of activity usually associated with positive emotions.

Was this high rate of activity a *result* of meditation, or simply a correlation unrelated to cause and effect? To find out, the researchers experimented, comparing “before” and “after” brain scans of volunteers who were not experienced meditators (Davidson et al., 2003). First, they took baseline scans of volunteers’ normal levels of brain activity. They then randomly assigned them either to a control group or to an eight-week course in *mindfulness meditation*, which has been shown to lessen anxiety and depression (Hofmann et al., 2010). Compared with both the control group and their own baseline, the meditation participants showed noticeably more left-hemisphere activity after the training, and they also had improved immune functioning. Such effects may help explain the results of another study, which found that hypertension patients assigned to meditation training had (compared with other treatment groups) a 30 percent lower cardiovascular death rate over the ensuing 19 years (Schneider et al., 2005). This benefit may result from the lessened anxiety and improved mood that accompanies meditation (Hofmann et al., 2010). The U.S. National Institutes of Health include relaxation and meditation techniques as part of complementary and alternative medicine. For more on that topic, see Thinking Critically About: Complementary and Alternative Medicine.

FAITH COMMUNITIES AND HEALTH**84-5**

What is the faith factor, and what are some possible explanations for the link between religious involvement and longevity?

A wealth of studies has revealed another curious correlation, called the *faith factor*. Religiously active people tend to live longer than those who are not religiously active. In the twenty-first century’s first decade alone, some 1800 studies explored connections between spirituality and health and healing (Koenig et al., 2011). In one study, researchers compared the death rates for 3900 Israelis living in either one of two groups of communities. The first group contained 11 religiously orthodox collective settlements; the second group contained 11 matched, nonreligious collective settlements (Kark et al., 1996). The researchers found that, over a 16-year period, “belonging to a religious collective was associated with a strong protective effect” not explained by age or economic differences. In every age group, religious community members were about half as likely to have died as were their nonreligious counterparts. This difference is roughly comparable to the gender difference in mortality.

Thinking Critically About

Complementary and Alternative Medicine

84-4 What is *complementary and alternative medicine*, and how is it best assessed through scientific research?

In China, herbal therapies have long flourished, as have acupuncture and acupressure therapies that claim to correct “imbalances of energy flow” (called Qi or Chi) at identifiable points close to the skin. In Germany, herbal remedies and homeopathy are popular. Such remedies are part of **complementary and alternative medicine (CAM)**, which also includes relaxation, massage therapy, spiritual healing, chiropractic, and aromatherapy. Facing political pressure to explore CAM techniques, the U.S. National Institutes of Health (NIH) established the National Center for Complementary and Alternative Medicine, which the center defines as health care treatments not taught widely in medical schools, not usually reimbursed by insurance companies, and not used in hospitals (**TABLE 84.1**).

complementary and alternative medicine (CAM)

as yet unproven health care treatments intended to supplement (complement) or serve as alternatives to conventional medicine, and which typically are not widely taught in medical schools, used in hospitals, or reimbursed by insurance companies. When research shows a therapy to be safe and effective, it usually then becomes part of accepted medical practice.

So what shall we make of CAM? Some aspects, such as lifestyle changes and stress management, have acknowledged validity. And certain techniques have proved useful for specific ailments, as acupuncture, massage therapy, and aromatherapy have for pain relief in cancer patients (Fellowes et al., 2004). Do the other aspects offer, as some believe, a new medical paradigm?

Critics point out that people consult physicians for diagnosable, curable diseases and turn to CAM techniques for either

TABLE 84.1
Five Domains of Complementary and Alternative Medicine

<i>Alternative medical systems</i>	Therapies used in place of conventional medicine, including homeopathy in Western cultures and traditional Chinese medicine and Ayurveda practices in non-Western cultures.
<i>Mind-body interventions</i>	Techniques designed to enhance the mind's capacity to affect bodily functions and symptoms, including meditation, prayer, mental healing, and therapies using creative outlets such as art, music, or dance.
<i>Biologically based therapies</i>	Therapies using natural substances such as herbs, foods, and vitamins.
<i>Manipulative and body-based methods</i>	Techniques such as chiropractic or osteopathic manipulation and massage therapy, which manipulate or move one or more body parts.
<i>Energy therapies</i>	Techniques using presumed energy fields. Biofield therapies, such as qi gong, Reiki, and therapeutic touch, are intended to affect energy fields that purportedly surround and penetrate the human body. Bioelectromagnetic-based therapies involve the unconventional use of electromagnetic fields, such as pulsed or magnetic fields.

Source: Adapted from the National Center for Complementary and Alternative Medicine, NIH <http://nccam.nih.gov/health/whatiscam>.

incurable illnesses or when well but feeling subpar. And given two influences—*spontaneous remission* and the *placebo effect*—CAM practices are bound to seem effective, whether they are or not. Thus, an otherwise healthy person with a cold may try an herbal remedy and then credit the natural disappearance of symptoms to CAM. During cyclical diseases, such as arthritis and allergies, CAM may seem especially effective as people seek therapy during the downturn and presume its effectiveness during the ensuing upturn.

The healing power of belief was clear in one German study of 302 migraine headache patients, which found that 51 percent of those receiving acupuncture treatment found relief, as did only 15 percent of those in a waiting list control group. But among a third group that received “sham acupuncture” (needles inserted at nonacupuncture points), 53 percent enjoyed relief. Such results indicate “a powerful placebo effect” (Linde et al., 2005).

(continued)

Thinking Critically About *(continued)*

As always, the way to discern what works and what does not is to experiment: Randomly assign patients to receive the therapy or a placebo control. Then ask the critical question: When neither the therapist nor the patient knows who is getting the real therapy, is the real therapy effective?

Much of today's mainstream medicine began as yesterday's alternative medicine. Natural botanical life has given us digitalis (from purple foxglove), morphine (from the opium poppy), and penicillin (from penicillium mold). In each case, the active ingredient was verified in controlled trials. We have medical and public health science to thank for the antibiotics, vaccines, surgical procedures, sanitation, and emergency

medicine that helped lengthen our life expectancy by three decades during the last century.

"CAM changes continually," notes the National Center for Complementary and Alternative Medicine (2006), "as those therapies that are proven to be safe and effective become adopted into conventional health care." Indeed, said *New England Journal of Medicine* editors Marcia Angell and Jerome Kassirer (1998), "There cannot be two kinds of medicine—conventional and alternative. There is only medicine that has been adequately tested and medicine that has not, medicine that works and medicine that may or may not work. Once a treatment has been tested rigorously, it no longer matters whether it was considered alternative at the outset."

How should we interpret such findings? Skeptical researchers remind us that correlations can leave many factors uncontrolled (Sloan et al., 1999, 2000, 2002, 2005). Here is one obvious possibility: Women are more religiously active than men, and women outlive men. Does religious involvement merely reflect this gender-longevity link? One 8-year study by the U.S. National Institutes of Health, for example, followed 92,395 women, ages 50 to 79. Even after controlling for many factors, women attending religious services weekly (or more) experienced an approximately 20 percent reduced risk of death during the study period (Schnall et al., 2010). But the association between religious involvement and life expectancy is also found among men (Benjamins et al., 2010; McCullough et al., 2000, 2005, 2009). A 28-year study that followed 5286 Californians found that, after controlling for age, gender, ethnicity, and education, frequent religious attenders were 36 percent less likely to have died in any year (**FIGURE 84.3**). In another 8-year controlled study of more than 20,000 people (Hummer et al., 1999), this effect translated into a life expectancy at age 20 of 83 years for frequent attenders at religious services and 75 years for infrequent attenders.

Figure 84.3

Predictors of longer life: Not smoking, frequent exercise, and regular religious attendance

Epidemiologist William Strawbridge and his co-workers (1997, 1999; Oman et al., 2002) followed 5286 Alameda, California, adults over 28 years. After adjusting for age and education, the researchers found that not smoking, regular exercise, and religious attendance all predicted a lowered risk of death in any given year. Women attending weekly religious services, for example, were only 54 percent as likely to die in a typical study year as were nonattenders.

These correlational findings do not indicate that nonattenders can add 8 years to their lives if they start attending services and change nothing. But the findings do indicate that religious involvement is a *predictor* of health and longevity, just as nonsmoking and exercise are. Can you imagine what intervening variables might account for the correlation?

First, religion promotes *self-control* (McCullough & Willoughby, 2009). Religiously active people therefore tend to have healthier lifestyles; they smoke and drink much less (Koenig & Vaillant, 2009; Park, 2007; Strawbridge et al., 2001). One Gallup survey of 550,000 Americans found that 15 percent of the very religious were smokers, as were 28 percent of those non-religious (Newport et al., 2010). But such lifestyle differences are not great enough to explain the dramatically reduced mortality in the religious settlements, say the Israeli researchers. In American studies, too, about 75 percent of the longevity difference remained when researchers controlled for unhealthy behaviors, such as inactivity and smoking (Musick et al., 1999).

Could *social support* explain the faith factor (Ai et al., 2007; George et al., 2002)? In Judaic, Christian, and Islamic religions, faith is a communal experience. To belong to one of these faith communities is to have access to a support network. Religiously active people are there for one another when misfortune strikes. Moreover, religion encourages marriage, another predictor of health and longevity. In the Israeli religious settlements, for example, divorce has been almost nonexistent. But even after controlling for social support, gender, unhealthy behaviors, and preexisting health problems, the mortality studies still find that religiously engaged people tend to live longer (Chida et al., 2009).

Researchers therefore speculate that a third set of intervening variables help protect religiously active people from stress and enhance their well-being. Those benefits may flow from a stable, coherent worldview, a sense of hope for the long-term future, feelings of ultimate acceptance, and the relaxed meditation of prayer or Sabbath observance (**FIGURE 84.4**). These variables might also help to explain other recent findings among the religiously active, such as healthier immune functioning, fewer hospital admissions, and, for AIDS patients, fewer stress hormones and longer survival (Ironson et al., 2002; Koenig & Larson, 1998; Lutgendorf et al., 2004).

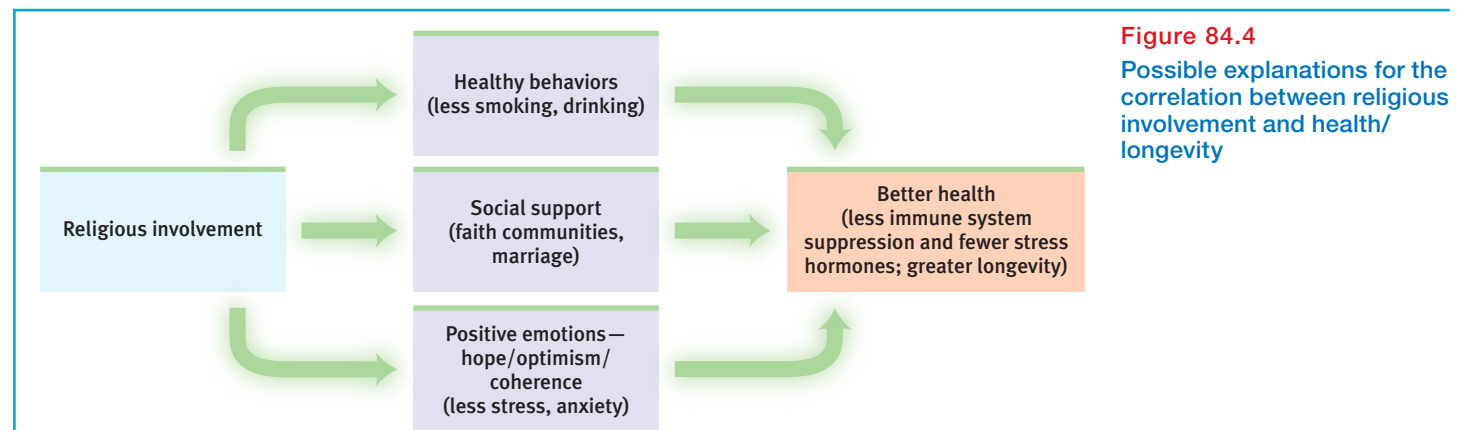

Figure 84.4
Possible explanations for the correlation between religious involvement and health/longevity

Before You Move On

▶ ASK YOURSELF

What techniques do you currently use to manage stress and promote health? In what ways might you improve your stress management and increase well-being?

▶ TEST YOURSELF

Those who frequently attend religious services live longer, on average, than those who attend infrequently or not at all. What type of research finding is this, and what explanations might it have?

Answers to the Test Yourself questions can be found in Appendix E at the end of the book.

Module 84 Review

84-1 What are the links among basic outlook on life, social support, stress, and health?

- Studies of people with an optimistic outlook show that their blood pressure does not increase as sharply in response to stress, their recovery from heart bypass surgery is faster, and their life expectancy is longer, compared with their pessimistic counterparts.
- Social support promotes health by calming us, reducing blood pressure and stress hormones, and by fostering stronger immune functioning.

84-2 How effective is aerobic exercise as a way to manage stress and improve well-being?

- *Aerobic exercise* is sustained, oxygen-consuming activity that increases heart and lung fitness.
- It increases arousal, leads to muscle relaxation and sounder sleep, triggers the production of neurotransmitters, and enhances self-image. It can relieve depression and, in later life, is associated with better cognitive functioning and longer life.

84-3 In what ways might relaxation and meditation influence stress and health?

- Relaxation and meditation have been shown to reduce stress by relaxing muscles, lowering blood pressure, improving immune functioning, and lessening anxiety and depression.

84-4 What is *complementary and alternative medicine*, and how is it best assessed through scientific research?

- *Complementary and alternative medicine (CAM)* comprises unproven health care treatments intended to serve as supplements or alternatives to conventional medicine; they are not widely taught in medical schools, used in hospitals, or reimbursed by insurance companies.
- To isolate real CAM treatment effects from placebo effects and spontaneous recovery influences, researchers experiment, randomly assigning people to experimental and control conditions.

84-5 What is the faith factor, and what are some possible explanations for the link between religious involvement and longevity?

- The faith factor is the finding that religiously active people tend to live longer than those who are not religiously active. Possible explanations may include the effect of intervening variables, such as the healthy behaviors, social support, or positive emotions often found among people who regularly attend religious services.

Multiple-Choice Questions

1. What kind of sustained, oxygen-consuming exercise increases heart and lung fitness?
 - a. Meditative
 - b. Aerobic
 - c. Alternative
 - d. Communal
 - e. Social
2. Which of the following best describes the group of remedies that include aromatherapy, spiritual healing, and relaxation?
 - a. Complementary and alternative medicine
 - b. Wellness
 - c. Social support
 - d. Optimism and health
 - e. Immune function support
3. In which complementary and alternative medicine domain would we find therapies such as herbs and vitamins?
 - a. Manipulative and body-based methods
 - b. Mind-body interventions
 - c. Alternative medical system
 - d. Biologically based therapies
 - e. Energy therapies

Practice FRQ

1. Describe three factors that may account for the relationship between religion and better health.

(3 points)

Module 85

Animal Thinking and Language

Module Learning Objectives

- 85-1** Describe what is known about thinking in other species.
- 85-2** Discuss what we know about other species' capacity for language.

Do Other Species Share Our Cognitive Skills?

- 85-1** What do we know about thinking in other species?

Other animals are smarter than we often realize. As the pioneering psychologist Margaret Floy Washburn explained in her 1908 book, *The Animal Mind*, animal consciousness and intelligence can be inferred from their behavior. Module 34 described animals displaying insight, but here are some other animal tricks.

USING CONCEPTS AND NUMBERS

Even pigeons—mere birdbrains—can sort objects (pictures of cars, cats, chairs, flowers) into categories, or concepts. Shown a picture of a never-before-seen chair, the pigeon will reliably peck a key that represents “chairs” (Wasserman, 1995). The great apes also form concepts, such as “cat” and “dog.” After monkeys learn these concepts, certain frontal lobe neurons in their brains fire in response to new “catlike” images, others to new “doglike” images (Freedman et al., 2001).

Until his death in 2007, Alex, an African Grey parrot, categorized and named objects (Pepperberg, 2006, 2009). Among his jaw-dropping numerical skills was the ability to comprehend numbers up to 6. He could speak the number of objects. He could add two small clusters of objects and announce the sum. He could indicate which of two numbers was greater. And he gave correct answers when shown various groups of objects. Asked, for example, “What color four?” (meaning “What’s the color of the objects of which there are four?”), he could speak the answer.

USING TOOLS AND TRANSMITTING CULTURE

Like humans, many other species invent behaviors and transmit cultural patterns to their peers and offspring (Boesch-Achermann & Boesch, 1993). Forest-dwelling chimpanzees select different tools for different purposes—a heavy stick for making holes, a light, flexible stick for fishing for termites (Sanz et al., 2004). They break off the reed or stick, strip off any leaves, carry it to a termite mound, twist it just so, and carefully remove it. Termites for lunch! (This is very reinforcing for a chimpanzee.) One anthropologist, trying to mimic the animal’s deft fishing moves, failed miserably.

Researchers have found at least 39 local customs related to chimpanzee tool use, grooming, and courtship (Whiten & Boesch, 2001). One group may slurp termites directly from a stick, another group may pluck them off individually. One group may break nuts with a stone

Gerald Searcy/Getty Images

hammer, another with a wooden hammer. These group differences, along with differing styles of communication and hunting, are not genetic; they are the chimpanzee version of cultural diversity. Several experiments have brought chimpanzee cultural transmission into the laboratory (Horner et al., 2006). If Chimpanzee A obtains food either by sliding or by lifting a door, Chimpanzee B will then typically do the same to get food. And so will Chimpanzee C after observing Chimpanzee B. Across a chain of six animals, chimpanzees see, and chimpanzees do. Other animals have also shown surprising cognitive talents (**FIGURE 85.1**).

Figure 85.1

Tool-using animals (a) New Caledonian crows studied by Christopher Bird and Nathan Emery (2009) quickly learned to raise the water level in a tube and nab a floating worm by dropping stones into the water. Other crows have used twigs to probe for insects, and bent strips of metal to reach food. (b) Capuchin monkeys have learned not only to use heavy rocks to crack open palm nuts, but also to test stone hammers and select a sturdier, less crumbly one (Visalberghi et al., 2009). (c) One male chimpanzee in Sweden's Furuviik Zoo was observed every morning collecting stones into a neat little pile, which later in the day he used as ammunition to pelt visitors (Osvath, 2009). (d) Dolphins form coalitions, cooperatively hunt, and learn tool use from one another (Bearzi & Stanford, 2010). This bottlenose dolphin in Shark Bay, Western Australia, belongs to a small group that uses marine sponges as protective nose guards when probing the sea floor for fish (Krützen et al., 2005).

(d)

OTHER COGNITIVE SKILLS

A baboon knows everyone's voice within its 80-member troop (Jolly, 2007). Sheep can recognize and remember individual faces (Morell, 2008). Chimpanzees and two species of monkeys can even read your intent. They would show more interest in a food container you have intentionally grasped rather than in one you flopped your hand on, as if by accident (Wood et al., 2007). Great apes and dolphins have demonstrated self-awareness by recognizing themselves in a mirror. So have elephants, which in tests also display their abilities to learn, remember, discriminate smells, empathize, cooperate, teach, and spontaneously use tools (Byrne et al., 2009). As social creatures, chimpanzees have shown altruism, cooperation, and group aggression. Like humans, they will kill their neighbor to gain land, and they grieve over dead relatives (Anderson et al., 2010; Biro et al., 2010; Mitani et al., 2010).

There is no question that other species display many remarkable cognitive skills. But one big question remains: Do they, like humans, exhibit language?

Do Other Species Have Language?

85-2 What do we know about other species' capacity for language?

Humans have long and proudly proclaimed that language sets us above all other animals. "When we study human language," asserted linguist Noam Chomsky (1972), "we are approaching what some might call the 'human essence,' the qualities of mind that are, so far as we know, unique [to humans]."

If in our use of language we humans are, as the psalmist long ago rhapsodized, “little lower than God,” where, then, do other animals fit in the scheme of things? Are they “little lower than humans”? Let’s see what research on animal language can tell us.

Without doubt, animals show impressive comprehension and communication. Consider vervet monkeys. They sound different alarm cries for different predators: a barking call for a leopard, a cough for an eagle, and a chattering for a snake. Hearing the leopard alarm, other vervets climb the nearest tree. Hearing the eagle alarm, they rush into the bushes. Hearing the snake chatter, they stand up and scan the ground (Byrne, 1991). To indicate such things as a type of threat—an eagle, leopard, falling tree, or neighboring group—monkeys will combine six different calls into a 25-call sequence (Balter, 2010). But is this language, in the sense that humans use language? This question has launched thousands of studies, most of them with chimpanzees.

In the late 1960s, psychologists Allen Gardner and Beatrix Gardner (1969) aroused enormous scientific and public interest when they built on chimpanzees’ natural tendencies for gestured communication and taught sign language to a chimpanzee named Washoe (c. 1965–2007). After 4 years, Washoe could use 132 signs; by her life’s end, she was using 245 signs (Metzler et al., 2010; Sanz et al., 1998). After moving to a Central Washington University primate center, Washoe and other chimpanzees showed continued vocabulary growth (Metzler et al., 2010).

During the 1970s, as more and more reports came in, it seemed apes might indeed be “little lower than human.” One *New York Times* reporter, having learned sign language from his deaf parents, visited Washoe and exclaimed, “Suddenly I realized I was conversing with a member of another species in my native tongue.” Other chimpanzees were stringing signs together to form sentences, as Washoe did, signing, “You me go out, please.” Some word combinations seemed very creative—saying *water bird* for “swan” or *elephant baby* for a long-nosed Pinocchio doll, or *apple-which-is-orange* for “orange” (Patterson, 1978; Rumbaugh, 1977).

Stephen Dunn/Allsport Jim Cummins/Getty Images

Talking hands Chimpanzees’ use of sign language builds upon their natural gestured words (such as a hand extended for “I want some”). Human language appears to have evolved from such gestured communications (Corballis, 2002, 2003; Pollick & de Waal, 2007). Even today, gestures are naturally associated with spontaneous speech, especially speech that has spatial content. Both gesture and speech communicate, and when they convey the same rather than different information (as they do in baseball’s sign language), we humans understand faster and more accurately (Hostetter, 2011; Kelly et al., 2010). Outfielder William Hoy, the first deaf player to join the major leagues (1892), invented hand signals for “Strike!” “Safe!” (shown here) and “Yerr out!” (Pollard, 1992). Referees in all sports now use invented signs, and fans are fluent in sports sign language.

By the late 1970s, some psychologists were growing skeptical. Were the chimps language champs or were the researchers chumps? Consider, said the skeptics:

- Ape vocabularies and sentences are simple, rather like those of a 2-year-old child. And unlike speaking or signing children, who easily soak up dozens of new words a week (and 60,000 by adulthood), apes gain their limited vocabularies only with great difficulty (Wynne, 2004, 2008). Saying that apes can learn language because they can sign words is like saying humans can fly because they can jump.
- Chimpanzees can make signs or push buttons in sequence to get a reward. But pigeons, too, can peck a sequence of keys to get grain (Straub et al., 1979). The apes’ signing might be nothing more than aping their trainers’ signs and learning that certain arm movements produce rewards (Terrace, 1979).

Comprehending canine Border collie Rico has a 200 (human) word vocabulary. If asked to retrieve a toy with a name he has never heard, Rico will pick out a new toy from a group of familiar items (Kaminski et al., 2004). Hearing that name for the second time four weeks later, Rico more often than not retrieves the same toy. Another border collie, Chaser, has set an animal record by learning 1022 object names (Pilley & Reid, 2011). Like a 3-year-old child, she can also categorize them by function and shape. She can “fetch a ball” or “fetch a doll.”

But is this language?

Chimpanzees’ ability to express themselves in American Sign Language (ASL) raises questions about the very nature of language. Here, the trainer is asking, “What is this?” The sign in response is “Baby.” Does the response constitute language?

- Studies of *perceptual set* (Module 17) show that when information is unclear, we tend to see what we want or expect to see. Interpreting chimpanzee signs as language may be little more than the trainers’ wishful thinking (Terrace, 1979). When Washoe signed *water bird*, she may have been separately naming *water* and *bird*.
- “Give orange me give eat orange me eat orange . . .” is a far cry from the exquisite syntax of a 3-year-old (Anderson, 2004; Pinker, 1995). To the child, “You tickle” and “Tickle you” communicate different ideas. A chimpanzee, lacking human syntax, might use the same sequence of signs for both phrases.

Controversy can stimulate progress, and in this case, it triggered more evidence of chimpanzees’ abilities to think and communicate. One surprising finding was that Washoe trained her adopted son Loulis to use the signs she had learned. It started like this. After her second infant died, Washoe became withdrawn when told, “Baby dead, baby gone, baby finished.” Two weeks later, researcher caretaker Roger Fouts (1992, 1997) signed better news: “I have baby for you.” Washoe reacted with instant excitement. Hair on end, she swaggered and panted while signing over and again, “Baby, my baby.” It took several hours for the foster mom and infant to warm to each other, but then Washoe broke the ice by signing, “Come baby” and cuddling Loulis. In the months that followed, Loulis, without human assistance, picked up 68 signs, simply by observing Washoe and three other language-trained chimps signing together.

Even more stunning was a report that Kanzi, a bonobo with a reported 384-word vocabulary, could understand syntax (rules of word order) in spoken English (Savage-Rumbaugh et al., 1993, 2009). Kanzi happened onto language while observing his adoptive mother during her language training. To someone who doesn’t understand syntax, “Can you show me the light?” and “Can you bring me the [flash]light?” and “Can you turn the light on?” might all seem the same. Kanzi, who appears to have the grammatical abilities of a human 2-year-old, knows the difference. Given stuffed animals and asked—for the first time—to “make the dog bite the snake,” he put the snake to the dog’s mouth.

So, how should we interpret these studies? Are humans the only language-using species? If by *language* we mean verbal or signed expression of complex grammar, most psychologists would now agree that humans alone possess language. If we mean, more simply, an ability to communicate through a meaningful sequence of symbols, then apes are indeed capable of language.

One thing is certain: Studies of animal language and thinking have moved psychologists toward a greater appreciation of other species, not only for the traits we share with them but also for their own remarkable abilities. In the past, many psychologists doubted that other species could plan, form concepts, count, use tools, show compassion, or use language (Thorpe, 1974). Today, thanks to animal researchers, we know better. It’s true that humans alone are capable of complex sentences. Moreover, 2½-year-old children display some

Paul Fusco/Magnum Photos

cognitive abilities, such as following an actor’s gaze to a target, that are unmatched even by chimpanzees (Herrmann et al., 2010). Nevertheless, other species do exhibit insight, show family loyalty, communicate with one another, care for one another, and transmit cultural patterns across generations. Accepting and working out what this means in terms of the moral rights of other animals is an unfinished task for our own thinking species.

Before You Move On

▶ ASK YOURSELF

Can you think of a time when you felt an animal was communicating with you? How might you put such intuition to a test?

▶ TEST YOURSELF

If your dog barks at a stranger at the front door, does this qualify as language? What if the dog yips in a telltale way to let you know she needs to go out?

Answers to the Test Yourself questions can be found in Appendix E at the end of the book.

Module 85 Review

85-1

What do we know about thinking in other species?

- Researchers make inferences about other species' consciousness and intelligence based on behavior. The main focus of such research has been the great apes, but other species have also been studied.
- Evidence to date shows that other species can use concepts, numbers, and tools, and they can transmit learning from one generation to the next (cultural transmission). They also show insight, self-awareness, altruism, cooperation, grief, and an ability to read intentions.

85-2

What do we know about other species' capacity for language?

- A number of great apes (mostly chimpanzees) have learned to communicate with humans by signing or by pushing buttons wired to a computer, have developed vocabularies of nearly 400 words, have communicated by stringing these words together, have taught their skills to younger animals, and have some understanding of syntax.
- But only humans communicate in complex sentences. Nevertheless, primates' and other animals' impressive abilities to think and communicate challenge humans to consider what this means about the moral rights of other species.

Multiple-Choice Questions

- Which of the following is an example of an animal using concepts?
 - A parrot correctly answers the question, "What color four?"
 - A dog identifies the scent of her owner.
 - A parrot learns to say phrases.
 - A dog fetches a thrown stick.
 - A parrot quiets when the cover is put over his cage at night.
- All of the following species have shown evidence of tool use except:

a. humans.	c. monkeys.	e. dogs.
b. crows.	d. dolphins.	
- Do species other than humans possess language?
 - Yes. Recent studies with chimpanzees have proven beyond doubt that they use language.
 - No. Animals have never shown language beyond the ability to recognize words.
 - The answer depends on how you define language.
 - No. Animals that seem to use language can only do so for a matter of days before loss of memory leads to rapid fading of language ability.
 - Yes. Animals can develop vocabularies similar to young children.

Practice FRQ

- Provide a specific example from the text of animal thinking, animal tool use, and animal language.

Appendix A: Practice AP[®]-Style Exam

- The Big Five model suggests that people can be rated along the dimensions of conscientiousness, agreeableness, neuroticism, openness, and extraversion. This theory is best associated with which of the following?
 - Trait theory
 - Psychodynamic theory
 - The cognitive approach
 - The humanistic approach
 - The biological approach
- Warren has a bacterial infection that has affected the ability of the rods in his eyes to function correctly. This should have the greatest impact on which of the following?
 - Visual clarity
 - Peripheral vision
 - Color vision
 - Hearing high-frequency sounds
 - Hearing low-frequency sounds
- Seeking out information that supports our previously held beliefs, while discounting information that questions those beliefs, is an obstacle to problem solving known as
 - functional fixedness.
 - a logical fallacy.
 - overconfidence.
 - mental set.
 - confirmation bias.
- Joe is taking a new job on the night shift next week. His supervisors have informed him that initially he may have some problems with his level of alertness and his memory as he adjusts to his new schedule. Joe's supervisors are sharing with Joe their knowledge of
 - circadian rhythms.
 - REM sleep.
 - sleep spindles.
 - the social clock.
 - NREM sleep.
- A researcher who is trying to determine how social-cultural changes might be correlated with the incidence of bipolar disorder would be most interested in which of the following?
 - The brain changes in a person with bipolar disorder as measured by a PET scan
 - Scientific measures of the heritability of the disorder
 - The correlation between rates of poverty and cases of the disorder
 - Neurotransmitter levels in patients diagnosed with the disorder
 - The number of close biological relatives who also suffer from mood disorders
- Zeina cocked her head to the side immediately when she heard the fire truck's siren. Turning her head enabled each ear to detect a slightly different intensity of sound, thus enabling her to determine the siren's
 - timbre.
 - pitch.
 - frequency.
 - location.
 - tone.
- A police officer who asks a witness to recall details about someone suspected of a crime would be asking the witness to
 - listen to recordings of several voices to determine if the suspect's voice is detected.
 - select the suspect from a visual lineup of several similar people.
 - describe the suspect's physical qualities to a police sketch artist.
 - determine if the suspect's motive for the shooting seems believable.
 - imagine a scenario in which the suspect could have acted in self-defense.
- People diagnosed with OCD suffer from compulsions. Which of the following is a compulsion?
 - Renee persistently thinks about the possible death of her loved ones.
 - Eric frequently worries that there may be germs on his hands.
 - Brianna has an ongoing worry that she might have left the oven on at home.
 - Stefan often feels great anxiety if things are not in exact order in his room.
 - Tyrik flips the light switch on and off seven times each time he walks in the front door.

9. When a person performs a heroic act solely for public praise, she is on which developmental level according to Lawrence Kohlberg?
- Preconventional
 - Postconventional
 - Conventional
 - Concrete operational
 - Formal operational
10. The bus driver was surprised when her first passenger asked her to turn the music down, because she thought the volume was fine. When the passenger said something, though, the driver realized the sound was too loud. The bus driver's initial indifference to the volume can best be understood because
- the volume was below her absolute threshold.
 - the driver had a decreased ability to determine the music's pitch.
 - the just noticeable difference of the music was too great.
 - the driver had adapted to the volume of the music.
 - the driver was using bottom-up processing instead of top-down processing.
11. A rat jumps each time it sees a green light flash, because the green light has always appeared just before an electric shock. In classical conditioning, the initial learning of the connection between the light and the shock is referred to as
- spontaneous recovery.
 - extinction.
 - generalization.
 - accommodation.
 - acquisition.
12. Which of the following examples is the best illustration of cognitive dissonance?
- The cult member who admires the leader of his group and follows the leader without doubt
 - The teacher who reprimands a student who she feels could do much better academically
 - The soldier who receives orders from a superior that violate his personal moral beliefs
 - The librarian who dreams of returning to graduate school to become a professor
 - The student who gives up trying to master calculus because it seems too hard
13. At their high school reunion, many attendees recalled exactly where they were 20 years before when they realized the school was on fire. Strong memories of an emotionally significant moment are referred to as
- flashbulb memories.
 - state-dependent memories.
 - short-term memories.
 - sensory memories.
 - critical period memories.
14. Of the following, which pair are both used to reveal activity in a person's brain?
- CT scan and PET scan
 - X-ray and fMRI
 - fMRI and MRI
 - PET scan and fMRI
 - CT scan and MRI
15. A therapist who believes in giving patients positive reinforcements when they behave appropriately is most likely to use which of the following techniques?
- Systematic desensitization
 - Token economy
 - Aversive conditioning
 - Transference
 - Exposure therapy
16. Phil complained to his doctor that the sleeping pill the doctor previously prescribed no longer was effective at the original dosage. To his doctor's dismay, Phil confided that he had been taking more than the recommended amount of the drug to get the same effect. Phil's increasing intake of the drug reflects the condition known as
- withdrawal.
 - sensory overload.
 - tolerance.
 - addiction.
 - REM rebound.
17. Students who have recently learned "correlation does not equal causation" should be most cautious of the findings in which news headline below?
- "Coffee drinkers live longer, surveys say."
 - "101-year-old man still healthy and happy."
 - "Flu shots lower the risk of infection by 87% in lab studies."
 - "Skim milk consumption tied to decreased neuron growth in studies of mice."
 - "Observers note men less likely than women to wash their hands in public restrooms."
18. The symptoms of schizophrenia can be categorized as positive or negative. Which of the following symptoms can be considered positive?
- Hallucinations
 - Flat affect
 - Social withdrawal
 - Catatonia
 - Toneless vocal patterns

19. Mary Ainsworth designed the “strange situation” experiment in order to determine
- how creative young children could be in novel environments.
 - whether children had developed a secure attachment to their mothers.
 - if children were more motivated by social anxiety than by peer pressure.
 - if the parenting style of mothers affected their children’s temperament.
 - if early signs of imprinting in young children could be reversed.
20. A principal wants to make this year’s Halloween night dance safer because of vandalism and inappropriate behavior in the gym last year. She decides to increase the lighting in the parking lots, ban students from wearing masks over their faces, and increase the number of video cameras near the gym. These ideas are most closely linked to the principle of
- group polarization.
 - social facilitation.
 - superordinate goals.
 - deindividuation.
 - minority influence.
21. Longitudinal studies suggest that certain characteristics of children, such as conscientiousness and self-control, were very stable when those children became adults. Psychologists use what term to refer to these aspects of personality that appear early in life and which appear to be stable?
- Schema
 - Reflex
 - Temperament
 - Fixation
 - Sensory adaptation
22. One way to determine if infants can perceive a certain stimulus is to measure how long they gaze at the item before looking away. Psychologists use what term to refer to the concept that infants tend to decrease their rate of responding when a stimulus is repeated and no longer novel?
- Sensory adaptation
 - Infantile amnesia
 - Perceptual set
 - Perceptual constancy
 - Habituation
23. An injury that leads to the loss of binocular vision would have the greatest impact on
- visual acuity.
 - color perception.
 - peripheral vision.
 - depth perception.
 - selective attention.
24. The stage of sleep in which an EEG would detect the bursts of rhythmic activity known as sleep spindles is called
- REM sleep.
 - NREM-1.
 - NREM-2.
 - NREM-3.
 - hypnagogic sleep.
25. Ulric’s doctor suggested that he consider moving to an area where there is greater sunlight or purchasing a light box that emits a bright light. Given these treatment options, Ulric’s doctor must have diagnosed Ulric with
- attention-deficit/hyperactivity disorder.
 - a seasonal pattern for depressive disorders or bipolar disorder.
 - posttraumatic stress disorder.
 - antisocial personality disorder.
 - agoraphobia.
26. Damage to which of the following brain areas would create the most difficulty in interpreting feelings of heat and cold?
- Motor cortex
 - Sensory cortex
 - Frontal lobe
 - Temporal lobe
 - Occipital lobe
27. A substance that interrupts neural transmission by fitting into a receptor site but not activating it, or by preventing another neurotransmitter from accessing the receptor site, is known as
- an agonist.
 - an antagonist.
 - an endorphin.
 - a hormone.
 - the synaptic cleft.
28. Which of the following coefficients reflects the strongest correlation between two variables?
- 0.42
 - −0.31
 - 0.74
 - −0.88
 - 0.86
29. After Donnie realized the “intruder” in his home was just his mother returning unexpectedly, his breathing began to slow down, his heart rate decreased, and his digestion began again. These changes were coordinated by the
- limbic system.
 - parasympathetic nervous system.
 - sympathetic nervous system.
 - afferent neurons.
 - efferent neurons.

- 30.** The oldest theory about human motivation, which focuses on unlearned, complex patterns of behavior present throughout a species, is known as
- arousal theory.
 - drive-reduction theory.
 - instinct theory.
 - extrinsic motivation.
 - the hierarchy of needs.
- 31.** Prefixes and suffixes are small groups of letters that when added to the beginning or ending of words alter the definition of those words. Prefixes and suffixes, then, are examples of
- phonemes.
 - morphemes.
 - algorithms.
 - accommodation.
 - assimilation.
- 32.** Which of the following most accurately describes a projective test?
- A test designed to reveal a person's inner ability to do a task he or she has not tried before.
 - A test that shows a person's true preferences, based on responses to multiple-choice questions.
 - A test that indicates the level of indifference to pain that a person experiences.
 - A test created to see if one has an anxiety-inducing problem, but is instead claiming that others have that problem.
 - A test that prompts a person to reveal hidden conflicts by responding to ambiguous stimuli.
- 33.** Mr. Winters is a trainer who encourages his clients to lose weight. Instead of simply rewarding them when their weight declines, he is rewarding them each time they behave in ways that would reduce weight: each time they exercise, decline high-calorie foods, or even take the stairs at work. Reinforcing each time one gets closer to a desired behavior is known as
- conforming.
 - extinguishing.
 - social loafing.
 - shaping.
 - classical conditioning.
- 34.** Often restaurants will require groups of eight or more to pay a tip of 18 percent. This is based on the belief that in larger parties, individuals will often leave a smaller tip because "someone else will pay more." These restaurant owners, then, are aware of the impact of
- the fundamental attribution error.
 - the power of the situation.
 - hindsight bias.
 - confirmation bias.
 - diffusion of responsibility.
- 35.** In a research study, Dr. Regalis has participants listen to different kinds of music while she uses a brain scan to examine their brain functioning. Dr. Regalis is most likely studying which part of the brain?
- Temporal lobe
 - Occipital lobe
 - Broca's area
 - Motor cortex
 - Corpus callosum
- 36.** As a patient experiences an anxiety attack, he may experience a series of changes that are coordinated by the sympathetic nervous system. Which one of the following would the patient experience?
- Decreased heart rate
 - Slower breathing
 - Decreased salivation
 - Constricted pupils
 - Increased rate of digestion
- 37.** Joanna's grandmother told her, "When we were little, we couldn't afford new clothes, so our mother made us dresses out of potato sacks." Joanna's great-grandmother's ability to envision how a potato sack could be used as material for a dress suggests that she was able to overcome
- confirmation bias.
 - functional fixedness.
 - algorithms.
 - divergent thinking.
 - belief bias.
- 38.** Research has found that individuals suffering from schizophrenia have an excess number of receptors for the neurotransmitter
- acetylcholine.
 - norepinephrine.
 - GABA.
 - dopamine.
 - serotonin.
- 39.** Modern psychodynamic counselors are likely to emphasize
- the role of the id, ego, and superego.
 - the importance of early childhood experiences.
 - long, intensive therapy sessions over a period of many years.
 - fixations that may have stemmed from repressed sexual urges.
 - a patient's responses to Rorschach inkblots.

40. Which of the following is an example of variable-ratio reinforcement?
- College acceptance letters arrive around the date of April 1.
 - Percy gives his dog a cookie whenever his dog walks by strangers without barking.
 - Esmeralda disliked the substitute teacher, so she scowled every time she looked at him.
 - Judy discovered a shark's tooth after several hours of searching for one on the beach.
 - When Stu had been working on his homework for one hour, his mother allowed him to go outside and play.
41. What perspective is sometimes referred to as the "third force," since it offered a more optimistic alternative to Freud's psychoanalysis and Skinner's behaviorism?
- Biological psychology
 - Humanistic psychology
 - Cognitive psychology
 - Evolutionary psychology
 - Social-cultural psychology
42. The type of therapy that is most likely to emphasize a social-cultural approach by focusing on the patient's environment is
- family therapy.
 - rational-emotive behavioral therapy.
 - cognitive therapy for depression.
 - psychopharmacological treatments.
 - aversive therapy.
43. Which part of the brain would be most involved in maintaining homeostasis in body temperature?
- Prefrontal cortex
 - Temporal lobe
 - Thalamus
 - Hypothalamus
 - Amygdala
44. Unexplained physical symptoms, including headaches, pain, and digestive problems, which cannot be explained by physical or mental causes, may be diagnosed as
- mood disorders.
 - personality disorders.
 - somatoform disorders.
 - dissociative disorders.
 - eating disorders.
45. A psychologist who uses aversive therapy to treat a child's bed-wetting problem is using which of the following approaches?
- Cognitive
 - Biological
 - Behavioral
 - Evolutionary
 - Social-cultural
46. Psychologist David Wechsler has created tests for adults and children that are designed to reveal their
- intelligence.
 - aptitude.
 - achievement.
 - personality characteristics.
 - symptoms of psychological disorders.
47. In order to follow the ethical principles for research as established by the APA, psychologists should
- recruit participants for experiments by placing ads in college newspapers.
 - publish the full results, including participant information, of their research online.
 - keep their operational definitions secret so that they cannot be copied by other researchers.
 - debrief the participants after the conclusion of the research.
 - allow minors to choose to be participants if they wish to.
48. Which of the following statements is most typical of the approach of a cognitive therapist?
- "Let's go back to your statement about your happiness as a child."
 - "When you say 'No one likes me' that's illogical, because you do have close friends."
 - "What I hear you saying is you are angry, and I can hear the frustration in your voice."
 - "I'm going to start teaching you to relax, and then we'll slowly deal with your phobia."
 - "I think that prescribing you an SSRI will increase your positive mood over the next few weeks."
49. Dr. Alscott has examined two sets of data from his research. In the first set, the standard deviation was very small, while in the second set there was a much larger standard deviation. Based on this information, what conclusion can be drawn from these two sets?
- The median was greater than the mean in the second set.
 - The mean was greater than the median in the second set.
 - The standard deviation in both sets revealed a positive correlation between the data.
 - Most data points were closer to the mean in the first set than in the second.
 - Most data points were closer to the mean in the second set than in the first.
50. "The curious paradox is that when I accept myself just as I am, then I can change." This core idea in humanistic psychology is a quotation from
- Sigmund Freud.
 - Carl Rogers.
 - Aaron Beck.
 - Carl Jung.
 - B. F. Skinner.

51. Hans Selye argued that our bodies produce a similar reaction to all kinds of stress, and the longer this response continues, the more exhausted we become. He named this process
- the opponent-process theory.
 - systematic desensitization.
 - general adaptation syndrome.
 - global assessment of functioning.
 - triarchic intelligence.
52. “Both the left and the right hemisphere may be conscious simultaneously in different, even in mutually conflicting, mental experiences that run along in parallel.” This quotation by neuropsychologist Roger Sperry refers to his Nobel Prize-winning research on the effects of severing which part of the brain?
- Amygdala
 - Brainstem
 - Corpus callosum
 - Thalamus
 - Pituitary gland
53. Martin Seligman developed the concept of learned helplessness, the tendency of organisms to give up in situations in which they feel their efforts make no difference. This concept is closely linked to which of the following psychological disorders?
- Agoraphobia
 - Schizophrenia
 - Depression
 - Generalized anxiety disorder
 - Histrionic personality disorder
54. John Watson’s development of the concept of behaviorism was influenced most strongly by the work of
- Wilhelm Wundt.
 - the Gestalt psychologists.
 - John Locke.
 - B. F. Skinner.
 - Ivan Pavlov.
55. Psychologists Walk and Gibson attempted to determine whether infants had developed the ability to perceive depth by
- having them crawl over what appeared to be a sharp ledge.
 - measuring how long they looked at novel stimuli.
 - throwing soft foam balls to them and seeing how they would react.
 - showing them a simulation of birds flying at their faces.
 - seeing if they reached for a toy when it was held slightly beyond the reach of their arms.
56. Systematic desensitization would most likely be used as a treatment for which of the following disorders?
- Arachnophobia
 - Schizophrenia
 - Bipolar disorder
 - Hypochondriasis
 - Tardive dyskinesia
57. A manager at an ice cream store wants to increase sales, so he creates a program to rank his employees’ sales. His goal is to give a cash prize each week to the employee who has sold the highest number of ice cream cones. His strategy is based on the idea of
- a personal fable.
 - intrinsic motivation.
 - extrinsic motivation.
 - the collective unconscious.
 - self-efficacy.
58. The fire alarm has gone off so many times in their new school that Susannah and Tia don’t even flinch when they hear it. In fact, they even remained in the school library during a fire drill because they assumed it was another malfunction. Their failure to respond like they once did to the fire alarm shows the process of
- acquisition.
 - discrimination.
 - accommodation.
 - extinction.
 - assimilation.
59. Dr. Anders wants to investigate how people of different ages communicate via the Internet, so she does an experiment with three groups of three different ages: 18–21, 47–50, and 75–78. Concurrently comparing how people of different ages behave is an example of which of the following kinds of research?
- Case study
 - Longitudinal
 - Cross-sectional
 - Factor analysis
 - Qualitative research
60. In studies, reminding female test-takers that women historically have done poorly on a similar test can lead to lower test performance—particularly when compared with the scores of women who weren’t given such information. This decline in performance is an example of
- stereotype threat.
 - hindsight bias.
 - the mere exposure effect.
 - social facilitation.
 - negative transference.

- 61.** Research suggests that there is a connection between parenting style and social skills. Children with lower scores on measures of social skills and self-esteem tend to have parents who are
- authoritative.
 - permissive.
 - authoritarian.
 - neglecting.
 - demonstrative.
- 62.** Dr. Kirk worked with the government to create new standards for people seeking jobs as airport security screeners, including assessments in the interview process, designs for the flow of the security process itself, and measures for evaluating the job performance of these screeners. Which career category best fits Dr. Kirk's work?
- Developmental
 - Clinical
 - Forensic
 - Industrial-organizational
 - Community
- 63.** Which emotion theory places the greatest emphasis on physiological changes happening first, which are then followed by an experience of an emotion?
- Schachter-Singer theory
 - James-Lange theory
 - Cannon-Bard theory
 - Arousal theory
 - Incentive theory
- 64.** Although the group of senior citizens beat the teenagers in a trivia contest based on history, they were not nearly as successful in a competition that required them to quickly learn the rules of a new video game. This is most likely due to the decline of which of the following as humans age?
- Learned helplessness
 - Cognitive dissonance
 - Fluid intelligence
 - Crystallized intelligence
 - Elaborative rehearsal
- 65.** Which of these statements is most accurate about REM sleep?
- These periods are the longest at the beginning of the sleep period, then get shorter through the night.
 - These periods are the shortest at the beginning of the sleep period, then get longer through the night.
 - During these periods, brain activity is as reduced as muscle activity.
 - The brainstem continues to pass on motor activity signals to the rest of the body during REM sleep.
 - The dreams during this stage are frequently interrupted by sleep spindles.
- 66.** Random-dot stereograms are pictures that have an image hidden among the dots. Humans can often see these hidden images because each eye has a slightly different image projected on its retina, allowing us to see depth. Which term best describes this process?
- Motion parallax
 - Convergence
 - Retinal disparity
 - Relative height
 - Linear perspective
- 67.** A therapist tells a CEO that the reason he yells and screams at his staff is due to behavior he learned as a child. When he was a child, he threw temper tantrums in order to get his way. What is the term for this defense mechanism?
- Regression
 - Reaction formation
 - Projection
 - Rationalization
 - Sublimation
- 68.** During a dental procedure, Xavier is injected with a drug that is designed to greatly reduce his pain by interfering with the sending of pain signals. At the neural level, the drug is preventing
- action potentials from being transmitted.
 - neurotransmitters from being reabsorbed by neurons.
 - potassium ions from being released at the terminal buttons.
 - pain signals from being clearly interpreted in the sensory cortex.
 - the myelin sheath from protecting the axon.
- 69.** A babysitter cuts a sandwich into three equal pieces, then keeps two and gives one to the child she is caring for. The child is upset that this is unfair, so the babysitter divides the child's piece into two. Since each of them now has two pieces, the child is content. According to Jean Piaget, this is because the child lacks
- accommodation.
 - assimilation.
 - formal operational knowledge.
 - sensorimotor ability.
 - conservation.
- 70.** A young gymnast works out many hours each day to prepare for a national competition. This schedule means that she has to forego opportunities to socialize with her peers, and makes it hard to have a romantic relationship. The gymnast's willingness to give up some kinds of affection in order to pursue athletic achievements is at odds with whose theory of human motivation?
- Abraham Maslow
 - Henry Murray
 - Philip Zimbardo
 - David McClelland
 - Solomon Asch

- 71.** Seven-year-old Daniel was able to see that the dot-to-dot puzzle was going to form a picture of a tiger even before he started drawing on the puzzle. Which Gestalt principle helped Daniel perceive the tiger from all the unconnected dots?
- Proximity
 - Continuity
 - Bipolar cues
 - Retinal disparity
 - Closure
- 72.** In an experiment by Stanley Schachter and Jerome Singer, participants labeled their arousal as joyous or irritable, depending on the people they were with. This experiment established that emotions are not only physiological but are also
- psychodynamic.
 - humanistic.
 - biological.
 - cognitive.
 - behavioral.
- 73.** A tumor cut off bloodflow to a small section of Gia's brain, and as a result she struggled to understand the words that were being spoken to her. The damage to Gia's brain was probably localized in her
- Wernicke's area.
 - Broca's area.
 - hippocampus.
 - hypothalamus.
 - brainstem.
- 74.** According to the behavioral perspective, the purpose of punishment is to
- make a person sorry for the behavior he has committed.
 - associate a positive consequence with a negative consequence.
 - make a behavior less likely to happen again.
 - allow the behavior to only occur again during a spontaneous recovery.
 - extinguish the response permanently.
- 75.** When Eli initially joined an online group against increased government spending, he only had mild views on the topic. If he continues in the group and rarely gets information from alternate sources with opposing views, what might be the outcome?
- He might become deindividuated and express views against the group's beliefs.
 - He might use social facilitation to spread the group's views more widely online.
 - He might use confirmation bias to seek out sources that challenge his beliefs.
 - His and the group members' views might become intensified over time.
 - His and the group members' views might begin to become more varied over time.
- 76.** When hiring for a new creative director for an advertising agency, Amina decided that the number one criteria she desired was a person who could devise numerous ways to solve problems. A person talented in this area would most likely be good at
- divergent thinking.
 - convergent thinking.
 - belief perseverance.
 - solving crossword puzzles.
 - doing arithmetic.
- 77.** The personality test that is based on the writings of Carl Jung is the
- Minnesota Multiphasic Personality Inventory.
 - Draw-A-Person test.
 - Rorschach inkblot test.
 - Thematic Apperception Test.
 - Myers-Briggs Type Indicator.
- 78.** Jason was watching the TV news and spotted a young man on a video running away from the police who were attempting to stop him. "He's running, so he must be a bad man," said Jason to his father. Jason's statement is an example of
- the availability heuristic.
 - the representativeness heuristic.
 - stereotype threat.
 - the fundamental attribution error.
 - cognitive dissonance.
- 79.** The sound of a sizzling steak or the smell of a warm apple pie might strongly tempt people to relish eating them. In the study of motivation, the sound and smell are considered to be
- incentives.
 - arousal-inducing.
 - drives.
 - self-actualization needs.
 - fixed action patterns.
- 80.** In the early twentieth century, French psychologists led by Alfred Binet developed the first test for intelligence to be given to French school children for the purpose of
- selecting the most capable to be trained as future leaders.
 - identifying those who might be wasting their talents and not taking school seriously.
 - testing whether French teachers merited higher pay.
 - evaluating the quality of French schools.
 - finding children who were struggling academically.

- 81.** “We were not surprised to discover that contact comfort was an important basic affectional or love variable, but we did not expect it to overshadow so completely the variable of nursing . . .” This quotation was written by which of the following psychologists?
- Harry Harlow
 - Konrad Lorenz
 - B. F. Skinner
 - John B. Watson
 - Mary Ainsworth
- 82.** An experimenter finds a difference between an experimental group and a control group that is less likely due to chance and more likely due to the manipulation of the independent variable. This finding then is most likely to be
- a replication.
 - statistically significant.
 - below the margin of error.
 - reliable, but not valid.
 - valid, but not reliable.
- 83.** The mere exposure effect reinforces the belief that the most important predictor in whether two people might be friends is
- similarity of religious and political views.
 - similar interests in the arts and culture.
 - their physical attractiveness.
 - their social status and level of income.
 - their proximity to each other.
- 84.** Albert Bandura believed that children could learn not only by doing behaviors themselves, but also by watching models perform those behaviors. His ideas expanded the idea of learning to include
- observational learning.
 - classical conditioning.
 - operant conditioning.
 - latent learning.
 - rote learning.
- 85.** Which of the following is an example of a self-fulfilling prophecy?
- David has had trouble in math in the past, so in his new math class he gives up on the first day.
 - Ivy does not think her teacher has treated her fairly, so she complains to her principal.
 - Samuel’s teacher puts him in a group with struggling students, and Samuel, normally a good student, responds by doing very poor work. The next week he is placed in the same group.
 - Rachel writes a letter to the editor about her concerns with the city council, and as a result her social studies teacher praises her in class.
 - Nyah’s father takes her out of an advanced class because she is struggling at first, but she responds by working even harder and making better grades in all of her classes.
- 86.** Noam Chomsky departed from B. F. Skinner’s beliefs about language, arguing that
- language is only possible during a critical period, and not afterward.
 - simple mastery of phonemes and morphemes does not equal a language.
 - the rules of syntax were more crucial to understanding language than semantics.
 - language is innate and not merely developed through reinforcement.
 - language is just as possible in animals as in humans, given enough time and training.
- 87.** Paul was unable to correctly identify the right shade of blue his wife wanted at the paint store, so he purchased various hues and brought them home. Apparently the ability to detect the varieties of the different blues fell below Paul’s
- signal detection.
 - absolute threshold.
 - difference threshold.
 - excitatory level.
 - inhibitory level.
- 88.** Teachers at York High School were dismayed at a new test they would be required to take to demonstrate their ability as educators. Rather than a test of content knowledge or of teaching techniques, the new test would measure their reaction time to a series of rapidly flashed abstract images and words. Despite the assurances of the test’s creator, the teachers argued that a test like this would have low
- content validity.
 - diagnostic validity.
 - split-half reliability.
 - test-retest reliability.
 - psychometric ratings.
- 89.** In Stanley Milgram’s experiments on obedience, he discovered that participants were less obedient when
- the person giving the orders was close at hand and was perceived to be a legitimate authority figure.
 - the authority figure was supported by a prestigious institution.
 - the victim was depersonalized or at a distance.
 - Milgram dissociated his experiments from Yale University.
 - there were no role models for defiance.
- 90.** The work of Elizabeth Loftus and other researchers has led to significant changes in the way courts and police officers think about
- the traumatic effects of solitary confinement.
 - whether patients with schizophrenia can be forced to take medication against their will.
 - whether the insanity defense is a legitimate method for handling legally insane individuals.
 - whether spouses should be forced to testify against their spouses on the witness stand.
 - the accuracy of eyewitness testimony and identification.

- 91.** The developmental theories of Lev Vygotsky differed from those of Jean Piaget in that Vygotsky
- emphasized the role of the social environment.
 - thought that Piaget ignored the psychosexual development of children.
 - questioned Piaget's focus on adult development.
 - focused more on moral development.
 - thought that the spiritual component of children's growth was essential.
- 92.** Dorothea Dix was a passionate advocate for
- reform in the treatment of the mentally ill.
 - the elimination of culturally-biased IQ tests.
 - identifying and reducing the self-fulfilling prophecy in schools.
 - changing the way disorders are classified in the DSM-5.
 - creating an alternative to the use of psychopharmacological medication.
- 93.** For those who focus on the biological approach, important evidence for whether someone who has been diagnosed with depression is improving is
- the quality of their statements about their own abilities and attitudes.
 - whether the number of contacts with their friends and families has increased.
 - whether they have begun to establish and work toward long-term goals.
 - whether the serotonin levels in their blood have increased.
 - if they have no suicidal thoughts or intentions.
- 94.** Instead of methodically poring through the atlas to find the correct map, Ivan just flipped to the section of the book where he thought it might be. Using a strategy based on a hunch rather than examining each page carefully involves the use of
- an algorithm.
 - a heuristic.
 - a syllogism.
 - insight.
 - framing.
- 95.** On the very first day of class, Mr. Boyarsky gave his students a test. When some complained, he responded that he wanted to know what their talents were, so he was giving them a test to predict what kind of skills they might learn best, and what kinds of jobs they might like to do one day. Mr. Boyarsky's test was
- an aptitude test.
 - an intelligence test.
 - an achievement test.
 - a personality test.
 - a projective test.
- 96.** When basketball star Michael Jordan graduated as one of a small number of geography majors from college, the average starting salary for a geography major soared by several hundred thousand dollars. In a situation like this, where a small amount of data greatly inflates the average, it is better to use which measure of central tendency?
- Mean
 - Median
 - Range
 - Standard deviation
 - Variation
- 97.** Damage to what part of a neuron might result in slowed or incomplete neural transmission along the axon?
- Cell body
 - Mitochondria
 - Dendrite
 - Myelin sheath
 - Synapse
- 98.** Dr. Warren is testing the link between the consumption of caffeine and a person's memory. She randomly divides 300 participants into three groups and gives each participant an energy drink to consume. Some of the drinks have high levels of caffeine, some have medium amounts, and some have none at all—but they all taste the same. About 30 minutes later, she has the participants play a memory game on the computer where they have to match faces and names together. At the end of the game, the computer thanks them for playing, and their scores are sent to Dr. Warren's lab. The dependent variable in the experiment is
- how quickly the participants matched the names and faces.
 - the participants' scores from the memory game.
 - the amount of caffeine they consumed.
 - their explanations about how they played the game.
 - the amount of caffeine they consume in a typical week.
- 99.** The independent variable in the experiment described in question 98 is
- how quickly the participants matched the names and faces.
 - the participants' scores from the memory game.
 - the amount of caffeine they consumed.
 - their explanations about how they played the game.
 - the amount of caffeine they consume in a typical week.
- 100.** A person who has an external locus of control is most likely to explain success or failure on a math test as due to
- how difficult the questions were.
 - whether he had effectively studied enough.
 - whether he had been able to understand the course material.
 - how well prepared he had been prior to taking the course.
 - the amount of time he had set aside to study.

Free-Response Questions

1. Psychology professors Elliott and Elizabeth are co-writing a book about what kinds of behaviors lead to feelings of happiness.
 - A. Explain what kinds of research studies Elliott and Elizabeth should look for as they investigate what kinds of behaviors cause feelings of happiness. Use the following terms in your explanation. Note: definitions alone will not score.
 - Experimental method
 - Correlational method
 - Operational definition
 - B. Discuss what Elliott and Elizabeth are likely to discover as they research psychological studies regarding the relationship between the following psychological factors and happiness.
 - REM sleep
 - Serotonin
 - Facial feedback effect
2. Charlie has been teaching for 25 years and was just assigned a student teacher, Randy. Charlie wants to advise Randy about effective teaching methods.
 - A. What advice should Charlie give Randy about the effectiveness of the following kinds of techniques and whether they might help motivate students in their classroom?
 - Classical conditioning
 - Positive reinforcement
 - Positive punishment
 - B. Randy is interested in teaching students study skills that will help them learn and retain information. Discuss how the following concepts might help or get in the way of effective studying.
 - Semantic encoding
 - State-dependent memory
 - Serial position effect
 - C. Finally, Charlie wants to advise Randy about how to develop a healthy classroom atmosphere. How could Charlie use the following concepts in his advice about building a useful classroom culture?
 - Ingroup bias
 - Superordinate goals

Appendix B: AP[®] Exam Tips

Unit I

Module 1

Page 2: To assist your active learning of psychology, Learning Objectives are grouped together at the start of each module, and then framed as questions that appear at the beginning of major sections.

Page 3: Every question on the AP[®] Psychology exam will reflect the fact that psychology is a science built on the tradition of Wundt and his laboratory. Correct answers on the test are based on what research has revealed; not on “common sense”!

Page 5: There are lots of important people in psychology. As you study, focus on the significance of their accomplishments. You are more likely to be tested on what a finding means than who discovered it.

Page 7: Memory research reveals a *testing effect*: We retain information much better if we actively retrieve it by self-testing and rehearsing. To bolster your learning and memory, take advantage of all the self-testing opportunities you’ll find throughout this text. These “Before You Move On” sections will appear at the end of each main section of text. The *Ask Yourself* questions will help you make the material more meaningful to your own life (and therefore more memorable). You can check your answers to the *Test Yourself* review questions in Appendix E at the end of the book.

Module 2

Page 9: Pay close attention to what David Myers, your author, is emphasizing as he tells the story of psychology. When he says the nature–nurture issue is the *biggest* question in psychology, that’s a sign. It’s a safe bet that this concept will be covered on the AP[®] exam.

Page 11: You will see versions of Figure 2.1 throughout the text. Spend some time right now familiarizing yourself with how the figure’s three corners might contribute to behavior or mental processes, the very stuff of psychology.

Page 12: These perspectives will come up again and again throughout your AP[®] Psychology course, and they *will* be on the exam. You need to become very comfortable with the meaning of terms like cognitive, behavioral, and psychodynamic. Ask your teacher for clarification if you are the least bit unclear about what the perspectives mean.

Page 14: Take careful note of the fact that psychiatry is a medical specialty and not a part of psychology. Can you summarize the similarities and differences among counseling psychologists, clinical psychologists, and psychiatrists?

Module 3

Page 20: You are about to read about a lot of career possibilities in psychology. Note the division between basic subfields and applied subfields. The work of some of these specialties is pretty obvious (it’s

not that hard to figure out in general what an educational psychologist or a health psychologist might do). Devote extra attention to those specialties that may be unfamiliar to you.

Page 21: *Educational psychologists* apply psychology’s findings in an effort to improve learning, and *school psychologists* assess and assist individual schoolchildren.

Unit II

Module 4

Page 32: It is quite common for multiple-choice questions on the AP[®] exam to test your knowledge of “media myths.” Pay particular attention when psychological findings run counter to “common sense.”

Module 5

Page 38: As you read this module, keep in mind that the scientific method is a set of principles and procedures, not a list of facts. You will be expected to understand how the science of psychology is done, not just what it has discovered.

Module 6

Page 47: This is the first of several times in your psychology course that you will see something labeled as being positive or negative. We often think that if something is positive it is good and if it’s negative it’s bad. That is rarely the case in this course. Here, positive and negative refer only to the direction of the correlation. They say nothing about whether the relationship is desirable or not.

Page 49: Take note of how much emphasis is put on this idea. Correlation and association do not prove a cause-effect relationship.

Page 52: The identification of independent variables (IV) and dependent variables (DV) is the single most likely concept to be tested on the AP[®] exam. Experiments are critical to psychology, and independent and dependent variables are critical to experiments.

Page 53: Almost 15 pages of text are summarized in Table 6.3. Spend some time with it, as it is information you will likely encounter on the AP[®] exam.

Module 7

Page 56: Do math and statistics scare you? Take a couple of deep breaths and relax before continuing. You will not be asked to do difficult computations on the AP[®] exam. Nothing will be beyond the scope of simple mental math. You need to focus on the concepts. Why do these statistics exist? How can they help us understand the real world?

Page 61: Sometimes a phrase that is frequently used in the media has a more specific meaning when used in psychology. That’s the case with the phrase “statistically significant.” Make sure you know the precise meaning.

Unit III

Module 9

Page 77: There is a ton of vocabulary in this unit. However, learning vocabulary is really not so hard: The secret is to work on it every day. Try flash cards. Work with a study buddy. Impress your non-psych friends with your new vocabulary. Just don't leave it until the night before the test. If you rehearse the vocabulary throughout the unit, you will do better on the unit test. The big bonus is that you will also retain far more information for the AP® exam.

Page 80: So far, you have been learning about how just one neuron operates. The action potential is the mechanism for communication *within* a single neuron. Now you are moving on to a discussion of two neurons and how communication occurs *between* them. Very different, but equally important.

Page 82: As the text indicates, there are dozens of different neurotransmitters. Though there's no way to predict exactly which ones you'll see on the AP® exam, it's quite possible that the ones in Table 9.1 are ones you'll be asked about.

Page 83: Be very clear on this. Neurotransmitters are produced inside the body. They can excite and inhibit neural communication. Drugs and other chemicals come from outside the body. They can have an agonistic effect or an antagonistic effect on neurotransmission.

Module 10

Page 87: You've heard the word peripheral before, right? How does your knowledge of peripheral vision help you understand what the peripheral nervous system is? It's always good to create mental linkages between what you're learning and what you already know.

Module 11

Page 96: Your author, David Myers, is about to take you on a journey through your brain. Focus on the name of each part, its location within the brain, and what it does. Then it's time to practice, practice, practice.

Page 99: If you ever have to make a guess about brain parts on the AP® exam, the hypothalamus isn't a bad bet. Even though it's small, it has many functions.

Module 13

Page 115: The classic split-brain studies are famous in psychology, which means they are likely to show up on the AP® exam.

Page 117: Notice that David Myers never refers to your left brain or your right brain. You have two brain hemispheres, each with its own responsibilities, *but you only have one brain*. It's very misleading when the media refers to the left brain and the right brain, and this happens frequently.

Page 119: Dual processing is another one of those big ideas that shows up in several units. Pay attention!

Module 14

Page 130: Heritability is likely to show up on the AP® exam because it's confusing. The key thing to remember is that heritability refers to variation within a group. It does not refer to the impact of nature on an individual. Be clear both on what it is and what it isn't.

Unit IV

Module 15

Page 153: You may wish to think about how the information on selective attention relates to something a little less dangerous: studying. The same principles apply. The more time you spend texting, tweeting, and Facebooking, the less focused you'll be on the material you're trying to master. A better strategy is to spend 25 minutes doing schoolwork and schoolwork alone. Then you can reward yourself with a few minutes of social networking.

Module 18

Page 173: There's a lot of vocabulary here. Make sure you understand the name and the function of each of the parts of the eye. To learn how all the parts fit together, it may help to make rough sketches (you don't need to be an artist to try this!) and then compare your sketches to Figures 18.3 and 18.4. You'll be better off making several quick, rough sketches than one time-consuming, nicely drawn one.

Page 175: Warning! Sometimes students spend so much time mastering the parts of the eye that they skim over the part you're about to read. Do not forget that you see with your brain as much as you see with your eyes.

Module 19

Page 182: The Necker cube is an excellent vehicle for understanding the distinction between sensation and perception. The only visual stimuli are the blue wedges. The circles, lines, and cube are all the products of perception—they are in your mind and not on the page.

Page 186: The illustrations in Figure 19.5 provide you with excellent opportunities to practice identifying monocular depth cues. To really demonstrate your understanding, look for these cues in other drawings and photographs. There are almost always cues to identify.

Module 20

Page 194: Pay attention to how many pages are devoted to each of the senses. Not only does this represent the complexity of the sensory system, it also represents how likely you are to find questions about that system on the AP® exam. More pages are devoted to vision than hearing, and vision questions are somewhat more likely to appear on the exam.

Page 195: Note that both light and sound travel in waves. In each case, the amplitude and length of the waves are important.

Unit V

Module 22

Page 219: Note that our modern-day understanding of the unconscious is very different from Sigmund Freud's theory of the unconscious (Module 55). Freud believed the unconscious was a hiding place for our most anxiety-provoking ideas and emotions, and that uncovering those hidden thoughts could lead to healing. Now, most psychologists simply view the unconscious track as one that operates without awareness. Make sure you keep these two ideas of the unconscious straight.

Page 220: Psychological research corrects the mistaken popular belief that hypnosis or other methods can be used to tap into a pure and complete memory bank. You will learn much more about how memory really works when you get to Unit VII.

Module 23

Page 228: Study this cycle of sleep carefully. One common mistake that students make is to believe that REM sleep comes directly after deep NREM-3 sleep. As you can see, it does not. Generally, NREM-2 follows NREM-3. Then comes REM.

Module 24

Page 236: Many students try to get by on less and less sleep to try to fit everything in. The irony is that if you stay up too late studying, it can be counterproductive. Sleep deprivation makes it difficult to concentrate and increases the likelihood you will make silly mistakes on tests. The impact on your immune system means you are more likely to get sick. To be the best student you can be, make sleep a priority.

Module 25

Page 248: These three categories—depressants, stimulants, and hallucinogens—are important. There are likely to be questions on the AP® exam that will require you to know how a particular psychoactive drug is classified.

Page 253: Figure 25.4 is an excellent review of how neurotransmitters work. If there is any part of this that you don't understand, head back to Module 9 for a complete explanation.

Unit VI

Module 26

Page 264: It's easy to confuse habituation with sensory adaptation, a concept from Unit IV. Recall that sensory adaptation occurs when one of your sensory systems stops registering the presence of an unchanging stimulus—when you go swimming in a cool pool, for example, the water no longer feels cool after you've been in for a few minutes. Habituation, like sensory adaptation, involves a diminished response, but in this case it's a form of learning rather than a function of the sensory system. If you're exposed to the same stimulus over and over, your response decreases. A friend might sneak up and startle you by yelling "Boo!" But you'll probably startle less when he tries it again two minutes later. That's habituation.

Page 269: Spontaneous recovery is, in fact, spontaneous. Notice that the extinguished conditioned response returns without any additional pairing with the unconditioned stimulus. It is not a form of acquisition.

Page 270: Generalization and discrimination are introduced in this module, but they don't just apply to classical conditioning. These two concepts will show up in other types of learning as well.

Module 27

Page 275: Don't be fooled by the fact that classical conditioning is presented before operant conditioning. Classical conditioning was

understood before operant conditioning, but operant conditioning has a larger impact on our day-to-day lives.

Page 280: The word "interval" in schedules of reinforcement means that an interval of time must pass before reinforcement. There is nothing the learner can do to shorten the interval. The word "ratio" refers to the ratio of responses to reinforcements. If the learner responds with greater frequency, there will be more reinforcements.

Page 281: Remember that *any kind of reinforcement* (positive, negative, primary, conditioned, immediate, delayed, continuous, or partial) encourages the behavior. *Any kind of punishment* discourages the behavior. Positive and negative do not refer to values—it's not that positive reinforcement (or punishment) is the good kind and negative is the bad. Think of positive and negative mathematically; a stimulus is added with positive reinforcement (or punishment) and a stimulus is subtracted with negative.

Module 28

Page 287: Notice how useful operant conditioning is. People with an understanding of the principles of operant conditioning possess a tremendous tool for changing behavior. If you don't like the way your friends, teachers, coaches, or parents behave, pay attention to the uses of operant conditioning!

Module 29

Page 292: In the middle of the twentieth century, behaviorism was the dominant perspective in psychology, with little attention paid to the influence of biology and cognition in learning. Now we know better. As you read through this module, notice how important biological and cognitive factors are for understanding learning.

Module 30

Page 304: Bandura's Bobo doll experiment is one of the most famous in psychology. It shows up frequently on the AP® exam.

Unit VII

Module 31

Page 318: The next three modules (31–33) deal with memory. Not only is this a significant topic on the AP® exam, it is also one of the most practical topics in psychology, especially if you're a student! Some of your preconceptions about memory may be accurate and some may not. As you read, think about how you can apply what you're learning in order to be a better student.

Page 319: You will see several versions of Figure 31.2 as you work your way through Modules 31, 32, and 33. Pay attention! This model may look confusing now, but will make more and more sense as its components are described in more detail.

Page 324: It's not the studying you do in May that will determine your success on the AP® exam; it's the studying you do now. It's a good idea to take a little time each week to quickly review material from earlier in the course. When was the last time you looked at information from the previous units?

Page 325: Are you often pressed for time? The most effective way to cut down on the amount of time you need to spend studying is to increase the meaningfulness of the material. If you can relate the material to your own life—and that’s pretty easy when you’re studying psychology—it takes less time to master it.

Module 32

Page 334: Figure 32.5 is an excellent summary. Why don’t you review it for a few minutes and then see how much of it you can reproduce on a piece of paper? That will give you a good assessment of which parts of the memory process you know and which parts you still need to work on.

Module 33

Page 342: Retrograde amnesia acts backward in time, just like when you choose a “retro” look for a party and wear clothes from an earlier time.

Page 345: Here’s the prefix “retro” again and it means exactly the same thing with interference that it did for amnesia. In both cases, they’re exerting an influence back in time.

Page 346: There are many references to Sigmund Freud in the text. Most of your knowledge of Freud probably came from popular culture, and it often conflicts with the discoveries of modern researchers. The AP® exam may test your understanding of researchers’ views of Freud.

Page 347: Read this entire section particularly carefully. Many people harbor misconceptions about how memory works, and a lot of the misconceptions are dealt with in the next few pages. Memory does *not* function like a video recorder!

Module 35

Page 361: There are several sample problems for you to enjoy in this section. It can be very interesting to ask several of your friends to try to solve them, too. Have them talk through the problem out loud and you will gain some understanding of the processes they are using.

Module 36

Page 373: It is sometimes challenging to keep these building blocks straight. Phonemes are sounds. It may help to remember that phones carry sounds. Morphemes have meaning, and both words begin with the letter *m*.

Page 376: You’ll notice that even though the brain was one of the major topics in Unit III, it keeps coming up. Each time it does provides you with an opportunity to go back and review what you learned previously about the brain. Rehearse frequently, and you will not have much to relearn before the AP® exam.

Unit VIII

Module 37

Page 390: The introduction to Module 37 is important, because it informs you how the whole module is organized. Read it carefully now and perhaps return to it as a review when you are through with the module.

Page 391: Note that this section illustrates psychology’s biological perspective.

Page 392: Read carefully! Homeostasis is *not* a motivation theory, but rather a biological principle that applies to some motivational theories (like drive-reduction).

Module 39

Page 408: The central principle here is that there are many biological processes that govern human behavior less rigidly than they govern the behavior of other species. Because of our highly developed brain, sex hormones have less control over our behavior than they do over other animals’ behavior.

Module 40

Page 415: Free-response questions on the AP® exam often ask students to apply psychological principles to real-life situations. It’s easy to imagine a question that deals with social media.

Module 41

Page 421: Be prepared for at least a multiple-choice question that tests your ability to tell the difference between the James-Lange theory and the Cannon-Bard theory.

Page 423: Note the connections here to previous units. This paragraph relates to the nature of consciousness. The next paragraph relates to sensation and perception.

Page 425: Table 41.1 is an excellent summary of the theories of emotion. They are presented in the order they appeared historically. Notice that cognition, a hugely important factor in the modern theories, is not mentioned in the first two theories.

Unit IX

Module 45

Page 462: All three of these issues are important for development. Nature and nurture, of course, weaves its way through almost every module. It is one of the topics most likely to be on the AP® exam.

Page 465: Almost every topic in psychology holds personal relevance, but development stands out. As you work your way through this unit, think of how the material relates to you, your relatives, and your friends. The more often you do this, the easier it will be to remember the material.

Module 46

Page 471: Note that maturation, to developmental psychologists, is a biological sequence. This is much more precise than the general notion that maturation means to become more adult-like.

Module 47

Page 476: Jean Piaget is such an important person in the history of psychology that it’s likely there will be at least one question about him on the AP® exam.

Page 479: Careful! *Egocentric* is not the same as egotistical. Egocentric means you can't take someone else's point of view. Egotistical means you're pretty full of yourself.

Page 483: One good way to master the developmental milestones in Piaget's theory is to see them in action. If you know children of various ages, you can test them using some of the ideas presented in this section. Hide a toy from an infant to see object permanence in action. Pour water between two differently shaped glasses to see if a preschooler understands conservation.

Module 48

Page 490: Note that temperament is a contribution from the nature side of the nature and nurture debate.

Page 496: It's understandable if you are struggling to remember the differences between authoritarian and authoritative—these words are exactly the same through the first nine letters! Maybe it will help to realize that authoritative parents will engage in a little more give and take, and that the words *give* and *authoritative* both end in the letters *ive*.

Module 49

Page 500: There is a lot of information in this section. One good way to process these differences and similarities between genders is to consider which facts fit prevailing stereotypes and which don't. You may even want to keep a list.

Module 51

Page 516: Kohlberg's is an important stage theory. There are often AP® exam questions on this topic. It's very important to understand that the stage you're in doesn't depend on *what* you decide to do (for example, steal the medicine), it depends on *why* you decide to do it.

Module 52

Page 519: This is not the only place in the book that the author discusses Erik Erikson's stage theory. For example, trust was discussed on page 492. Integrity comes up on page 548. Table 52.1 pulls it all together in one place for you.

Page 521: Careful! In the media, to describe a relationship as intimate usually implies that it is sexual. Erikson means something different. In his theory, an intimate relationship may or may not be sexual (and a sexual relationship may or may not be intimate).

Module 54

Page 542: This section is a good example of the complexity of seemingly simple questions. It seems like one should be able to answer a question like "Does memory decline with age?" with a straightforward *yes* or *no*. People are complex. Development is complex. We should not be surprised to learn that many factors influence memory in adulthood.

Unit X

Module 55

Page 557: The boldfaced key terms that you read in this module are all quite famous terms. Even though modern psychology rejects

many of the specifics of psychoanalysis, the fame of Freud's concepts makes them likely topics for AP® exam questions.

Page 558: Be careful: It's easy to confuse Freud's three layers of the mind (conscious, preconscious, and unconscious) with the three parts of personality (id, ego, superego).

Page 561: The lines between these defense mechanisms aren't always clear. For example, *repression* can be found in almost every example. Focus on the key feature of each given example. If the key feature is seeing your own impulse in someone else, it's projection. If the key feature is shifting your aggression from one target to another, it's displacement.

Module 56

Page 568: It's very important to understand the differences between Freud's view of the unconscious and modern psychology's view of the unconscious. Read this section carefully.

Module 57

Page 573: Frequently, terms that begin with "self-" (like *self-actualization* or *self-concept*) are terms that are grounded in the humanistic perspective.

Module 58

Page 578: You are not likely to be asked questions about the specific traits in Figure 58.1. Focus instead on the two main dimensions (extraversion–introversion and stability–instability), and use the traits to get a sense of what the main dimensions mean. For example, stable people demonstrate leadership, and they are calm, even-tempered, and carefree.

Page 578: This is the third time you've encountered the idea of assessing personality. As with the psychodynamic and humanistic theories, psychologists working from the trait perspective have also tried to establish their own unique ways of measuring personality—in this instance by measuring our traits. There are scientifically sound *personality inventories* in use in psychological research, but beware of the hundreds of self-assessments available online that are neither reliable nor valid.

Page 581: Table 58.1 is an excellent summary of the Big Five personality factors and what they mean.

Module 59

Page 592: Tables 59.1 and 59.2 summarize a whole unit's worth of information. Study them well to be clear on the distinctions separating the major approaches to personality.

Page 595: It's important to note the difference between *self-esteem* and *self-efficacy*. Although your feeling of self-worth might be related to your beliefs about how competent you are, they are not the same thing.

Unit XI

Module 60

Page 608: David Myers identified three "huge controversies" in the unit opener. All three are covered extensively in this book, and all three will probably show up on the AP® exam.

Page 613: Do not continue on if you can't remember what terms like *MRI*, *parietal lobe*, and *axon* mean. Now is the time to head back to Unit III for a review. If you do this sort of review frequently, you'll have much better command of the material on the day of the AP® exam.

Module 61

Page 619: David Myers did not use the terms *nature* or *nurture* as he described the contributions of Binet and Terman, but he dropped many hints that should allow you to figure out who leaned toward the nature position and who leaned toward the nurture position. Can you do it?

Page 621: Can you remember why the intelligence test scores in Figure 61.2 are marked off in 15-point intervals? Do the 68 percent and 95 percent areas seem familiar? They should—you've seen this graph before. It's Figure 7.3 from the module on statistical reasoning. Intelligence tests are being used to illustrate that 68 percent of a population will be within one standard deviation of the mean for normally distributed data. Ninety-five percent will be within two standard deviations.

Page 622: Be careful! The terms *reliability* and *validity* have more precise meanings to psychologists than they do to the general public.

Module 63

Page 633: Figure 63.1 is worth spending some time on. Try grabbing a study buddy and explaining whether each of the five conditions provides more support for nature or more for nurture. In most cases, it's some of each and you have to look at comparisons between categories to really be able to draw conclusions.

Unit XII

Module 65

Page 656: Notice that the term “insanity” comes out of the legal system. It is not a psychological or medical diagnosis and does not appear in DSM-5.

Module 66

Page 662: The way disorders are classified can be confusing, so it's worth taking some time to keep the organization straight. Sometimes, there is a broad classification that includes more specific disorders—the broad category of anxiety disorders, for example, includes generalized anxiety disorder, panic disorder, and phobia. Other times, there is just one level of classification. Obsessive-compulsive disorder and posttraumatic stress disorder do not fit into broader categories.

Page 666: This is a good time to return to Unit VI and review the principles of classical and operant conditioning.

Module 67

Page 678: You can review brain scanning techniques, neurotransmitters, and brain parts in Unit III.

Module 68

Page 684: It is common for the AP® Psychology exam to include items to see if you are aware of various “media myths” about psychology. One of the most common of these myths is that schizophrenia means

split or multiple personality. Read this section carefully to achieve an accurate understanding of what schizophrenia is—and isn't.

Page 685: Are you clear about the difference between delusions and hallucinations? Delusions are false *thoughts*. Hallucinations are false *sensory experiences*.

Module 69

Page 699: Notice how different antisocial personality disorder is from the other disorders you have studied in this unit. Because individuals with antisocial personality disorder so often behave badly (according to society's standards of right and wrong), they tend to be viewed differently than people with disorders like depression or phobia.

Unit XIII

Module 70

Page 709: Most of the treatments discussed in this unit come from the perspectives you've been dealing with since Unit I. As you reach each major section—like the upcoming one on psychoanalytic and psychodynamic therapy—try to anticipate how someone from that perspective would approach therapy (in other words, “What would Freud do?”). This should help you organize and retain the information as you read.

Page 710: Psychoanalytic treatment is the public image of psychology. If you were to ask people to sketch a psychologist at work, you would see lots of sketches of therapists taking notes while they were seated behind patients on couches. Keep in mind that most therapy nowadays is very different from this image, and psychology careers stretch well beyond therapy.

Page 712: You can remember Acceptance, Genuineness, and Empathy as “AGE.”

Module 71

Page 716: Before you read the next several pages, you may want to quickly review the material on classical and operant conditioning in Unit VI.

Page 720: Behavior therapies focus on what you do. Cognitive therapies focus on what you think. That's a very basic distinction, but critically important for your understanding.

Module 72

Page 731: You will need to understand what basic statistical concepts are, but you will not need to do any actual calculations on the AP® exam.

Module 73

Page 741: The discussion of drug therapies is a great opportunity for you to review information about neurotransmitters and brain function. See Unit III if you need to brush up on these topics.

Unit XIV

Module 74

Page 754: Many students have not heard of the *fundamental attribution error* before taking a course in psychology. This concept often shows up on the AP® exam, so be sure you understand this well.

Module 75

Page 765: Three of the most famous research projects in psychology were done by social psychologists, and you've now read about them all. Milgram, Asch, and Zimbardo (from the last module) are all likely to appear on the AP® exam.

Module 76

Page 771: As you work through this material, identify examples in your own life. Then, compare your examples with a classmate's. This is a great way to make psychology come alive and to study effectively.

Module 77

Page 781: It's worth spending a little time focusing on the distinction between discrimination and prejudice. They are related, but different. The most important thing to note is that prejudice is cognitive in nature. Discrimination, on the other hand, is behavior motivated by prejudice.

Page 785: Pause for a minute and try to identify examples of the just-world phenomenon, in-group bias, and scapegoating in your own school. Are there a few or a lot?

Module 78

Page 789: Notice that you're back to a nature and nurture analysis again. The biology section is, of course, the nature component. When you get to the psychological and social-cultural factors in a few pages, that's nurture.

Page 792: Dave Myers points out that this section is an application of material that was introduced in Unit VI. You should go back there for a quick review if you don't recognize the basic components of operant conditioning and observational learning in this material.

Page 793: In the experiment described here, can you identify the independent and dependent variables? It's great practice to do this every time you read about an experiment.

Module 79

Page 798: Can you remember the other use of the term *proximity* earlier in the course? It was one of the Gestalt principles from Unit IV, Sensation and Perception.

Module 80

Page 808: Common sense suggests that you would be more likely to get help if there are more people around, but research on the bystander effect has in fact shown just the opposite is true. This concept often shows up on the AP® exam, so be sure you understand it.

APPENDIX D: Preparing for Further Psychology Studies

This appendix was written by Jennifer Zwolinski, University of San Diego.

As noted in Module 3, there is much that you can do with a psychology degree. In that module you learned about the work different types of psychologists do and where they do it. You are in the right place here for answers to important questions about pursuing the study of psychology: Will psychology be the right major for you? What are the various levels of psychology education, and what kinds of jobs are available at those levels? What are some ways you can improve your chances of admission to graduate school?

The Psychology Major

How Do You Know If Psychology Is the Right Major for You?

You can start by answering these questions to see if you would be well matched with a major in psychology. Do you

- enjoy learning about how and why we think and behave in the ways we do?
- appreciate the value of applying the scientific method to answer questions?
- have an interest in a career that requires interpersonal skills?
- want to learn critical thinking and analytical skills?
- want to learn communication and presentation skills?
- want to gain computer skills in data processing and skills in research methodology, such as assessment and statistics?
- want to work in human or animal services?
- have a desire to apply psychological principles to understand or solve personal, social, organizational, or environmental problems?

If you answered *Yes* to most or all of these questions, then psychology may be the right major for you.

How Popular Is the Psychology Major?

Psychology is a very popular major. After business and accounting majors (13 percent and 8 percent, respectively), psychology, nursing, and elementary education are tied for the third most popular majors (each 4 percent of all majors) (Carnevale et al., 2011). In 2008, more than 92,000 psychology majors graduated with a bachelor's degree in psychology from U.S. colleges and universities (Mulvey & Grus, 2010) (**FIGURE D.1**).

Figure D.1
Number of psychology degrees conferred by level of degree, 2008. Adapted from APA Center for Workforce Studies, January 2010. Source: U.S. Dept. of Education, National Center for Education Statistics, Integrated Postsecondary Data System Completion Survey. Note: Doctorate degree includes Psy.D.

Who Is Studying Psychology at the Undergraduate and Graduate Levels?

From 2008 to 2009, 77 percent of those graduating with bachelor's degrees in psychology were women. This tendency for most degree recipients in psychology to be women was also observed for master's degrees (80 percent) and doctoral degrees (73 percent). Women were most likely to earn specialized doctorate degrees in developmental and child psychology, whereas men were somewhat more likely to focus on cognitive and psycholinguistic psychology (U.S. Department of Education, National Center for Education Statistics, 2010) (**FIGURE D.2**).

Figure D.2

Psychology doctorate degrees awarded by subfield and sex, 2009

Adapted from APA Center for Workforce Studies, January 2011. Sources: NSF/NIH/USED/USDA/NEH/NASA, 2009 Survey of Earned Doctorates.

What Are the Main Reasons That Undergraduate Students Choose to Study Psychology?

One study found that the number one reason psychology majors chose their major was a positive experience in their introduction to psychology course (Marrs et al., 2007). Other research has found that the top five reasons students choose a psychology major are because it provides the ability to help others, incorporates interesting subject matter, produces a better understanding of self and others, includes good career or salary potential, and offers the ability to conduct research (Mulvey & Grus, 2010).

What Types of Skills Will You Learn as a Psychology Major?

Studies suggest that psychology majors learn a set of skills not offered by other social science majors. These include communication, information gathering, interpersonal management, and research methodology (Kruger & Zechmeister, 2001, as cited in Wegenek & Buskist, 2010).

The psychology major's skill set prepares graduates for numerous opportunities in the professional world and a range of graduate training options. The skills include an ability to work and get along with others, a desire and willingness to learn new things, adaptability to changing situations, and a capacity for problem solving (Landrum, 2001). Psychology majors also have a number of methodological skills that result from their focus on the scientific study of human and animal behavior. The study of statistics and research methodology contributes to a scientific mind-set that emphasizes exploring and managing uncertainty, critical thinking and analytical skills, and logical thinking abilities. Being able to analyze data using statistics, conduct database searches, and integrate multiple sources of information is helpful in a number of professional settings. Prospective employers appreciate the excellent written and verbal communication skills among students who master American Psychological Association (APA) style and present their research projects at conferences.

Career Options With a Degree in Psychology

What Can You Do With a Bachelor's Degree in Psychology?

If you major in psychology, you will have several possible career paths to follow. First, you might consider employment after graduation in a variety of professional settings. Here are the top five occupations for graduates with a bachelor's degree in psychology (Carnevale et al., 2011):

1. Management
2. Office work
3. Community Service
4. Sales
5. Education

Here are the top five industries in which graduates with a bachelor's degree in psychology may be found working (Carnevale et al., 2011):

1. Health service
2. Education
3. Financial services
4. Public administration
5. Professional services

If you choose to work more directly in the field of psychology, a bachelor's degree will qualify you to work as an assistant to psychologists, researchers, or other professionals in community mental health centers, vocational rehabilitation offices, and correctional programs (U.S. Bureau of Labor Statistics, 2012).

A second option for psychology majors is to pursue a master's degree or doctorate in psychology. Snyder and Dillow (2010) estimate that 20 to 24 percent of psychology baccalaureate recipients continue on to study psychology in graduate school (approximately 8 to 10 percent pursue doctorates).

A third option is to pursue advanced training in other disciplines, such as law, business, education, or medicine.

Drew Appleby and his colleagues (2010) prepared a list of 171 careers that would be of interest to psychology majors—including those pursuing advanced degrees. The list (see www.tinyurl.com/PsychologyCareers) includes links for more information about professional responsibilities, salaries, and job outlook for each of these positions.

How Can You Maximize Your College Success and Later Job Prospects With a Major in Psychology?

There are some things that all psychology majors can do to maximize success in college and, later, in the job market. Employers who hire people with only a bachelor's degree tend to favor individuals with strong interpersonal skills and practical experience as well as a good education (Cannon, 2005). It's not too early for you to begin planning how you can use your upcoming college education to improve your chances for success after college. Betsy Morgan and Ann Korschen (2009) offer the following helpful tips for succeeding in college and increasing your chances of getting a job after graduation. Many of these tools will benefit students who plan to apply to graduate school as well.

1. *Get to know your instructors.* Talk with them about the field of psychology and get their advice on your career plan. Ask them to support you on an independent study internship or research project. By learning more about your skills and future aims, faculty members can help you accomplish your goals. This may even result in an enthusiastic reference for future employment.
2. *Familiarize yourself with available resources, such as campus career services and alumni.* If you are searching for a part-time job during your studies (or a full-time job after graduation), career services can help you to identify and market your job skills and to emphasize the knowledge and abilities you have in your resume. They can also help you to network with other alumni who are working in your area of interest and who can help you prepare for the career that you want.
3. *Volunteer some of your time and talent to campus or community organizations, such as Psi Chi (the International Honor Society in Psychology) or your college's psychology club.* In addition to showing that you are an active citizen in your department, you will gain important skills, such as meeting and event planning, how to work with a group, and improved communication skills, all of which enhance your marketability.

On the job with a B.A. There are psychology-related jobs available even for those with only a B.A. degree. For example, this case manager working for a mental health organization in Florida is conducting a survey of the homeless people in her county in order to consider the best ways to address their needs.

4. *Participate in an internship experience.* Many employers want students to gain relevant experience outside the classroom. Internships are offered during the school year and during the summer break. Some are paid and others are not, but you may be able to earn course credit while completing an internship. In addition to trying out a possible career and gaining relevant work experience before you graduate, you will increase your support network of mentors who can provide supervision and support for your career goals. And you may be able to request letters of support when you apply for jobs or to graduate school.
5. *Take courses that support your interests.* Although the psychology major offers a range of skills that will benefit you, don't assume the psychology curriculum will offer all the skills necessary in your area of interest. Add courses to increase your knowledge base and skills. This will show prospective employers that your specific interests are in line with the demands of the job.

What Type of Salary Can You Expect With a Degree in Psychology? Will a Graduate Degree Increase Your Salary?

A 2009 study found that earnings increase with education and that higher levels of educational attainment will almost always yield greater financial rewards (Carnevale et al., 2011). Although these figures will be dated by the time you read this, they still provide a basis of comparison. In 2009, the median salary for psychology majors with a bachelor's degree was \$45,000. When considering baccalaureates from 171 majors, the median earnings varied greatly—from \$29,000 for counseling psychology majors to \$120,000 for petroleum engineering majors.

When considering new doctoral recipients in 2009, the overall median starting salary was \$64,000. Women reported a median salary that was \$8,000 lower than that reported by men (\$62,000 versus \$70,000, respectively). Median salaries reported by ethnic minorities were similar to those indicated by nonminorities: \$65,000 (Michalski et al., 2011).

Among psychologists with new doctoral level degrees in 2009, clinical psychologists working in criminal justice earned the highest median starting salary, \$80,500. Psychology graduates with doctoral degrees working in consulting firms (\$75,000) and those working in applied psychology positions (\$73,332) tended to have the next two highest median salaries (Michalski et al., 2011).

Of course, earning potential should not be the only reason that individuals choose a major. Job satisfaction is another important consideration.

What Kind of Job Satisfaction Can You Expect If You Are Working in a Psychology Field?

In a study of 27,000 Americans, the most satisfying jobs were found to be those that involve "caring for, teaching and protecting others and creative pursuits" (Smith, 2007, pp. 1–2). Most of the occupations with the highest-ranking happiness levels among workers involved helping others, using technical and scientific expertise, or using creativity (pp. 1–2). A bachelor's degree in psychology can increase the likelihood that you will be working in a job that fosters these skills (Landrum, 2009).

Positive job satisfaction has also been observed among individuals who attend graduate school in psychology. In 2009, 72 percent of new doctorate recipients indicated that their primary occupational position was their first choice. Most new graduates with a Ph.D. are fairly satisfied with their current position in terms of salary, benefits, opportunities for personal development, supervisors, colleagues, and working conditions (Michalski et al., 2011).

Postgraduate Degrees

In addition to a higher salary and strong job satisfaction, a graduate degree in psychology will give you proficiency in an area of psychological specialization. According to the U.S. Bureau of Labor Statistics (2012), psychologists with advanced degrees held approximately 174,000 jobs in 2010. Employment for psychologists is expected to grow 22 percent from 2010 to 2020, which is faster than the average for all occupations.

What's the Difference Between a Master's Degree and a Doctorate Degree in Psychology?

Both degrees will prepare you for more specialized training in psychology and open your job opportunities in the field of psychology beyond the bachelor's degree. However, the work settings for individuals with a psychology degree vary somewhat by type of graduate degree. Psychologists with a doctorate work primarily in universities and colleges; most people with a master's degree work in other educational institutions (such as elementary and secondary schools) and in for-profit companies (Mulvey & Grus, 2010) (**FIGURE D.3**).

You might acquire a master's degree to do specialized work in psychology. A master's requires at least two years of full-time graduate study in a specific subfield of psychology. In addition to specialized course work, requirements usually include practical experience in an applied setting and/or a master's thesis on an original research project. As a graduate with a master's degree, you might handle research and data collection and analysis in a university, government, or private industry setting. You might work under the supervision of a psychologist with a doctorate, providing some clinical service such as therapy or testing. Or you might find a job in the health, government, industry, or education fields. You might also acquire a master's degree as a stepping stone for more advanced study in a doctoral program in psychology, which will considerably expand the number of employment opportunities available to you (Super & Super, 2001).

You will probably need five to seven years of graduate study in a specific subfield of psychology to get your doctoral degree. The degree you choose to pursue will depend on your career goals. You will probably choose to earn a doctor of philosophy (Ph.D.) in psychology if your career goals are geared toward conducting research, or possibly a doctor of psychology (Psy.D.) if you are more interested in pursuing professional practice (clinical or therapeutic work). Training for the Ph.D. culminates in a dissertation (an extensive research paper you will be required to defend orally) based on original research. Courses in quantitative research methods, which include the use of computer-based analysis, are an important part of graduate study and are necessary to complete the dissertation. Psy.D. training may be based on clinical work and examinations rather than a dissertation. It is important to note, however, that psychologists with Psy.D. degrees are not the only ones who work in professional practice. Many psychologists who earn a Ph.D. in clinical or counseling psychology

BSIP/UG Via Getty Images

Clinician in training Those interested in professional practice can obtain either a Ph.D. in clinical or counseling psychology, or a Psy.D., which focuses on clinical or therapeutic work.

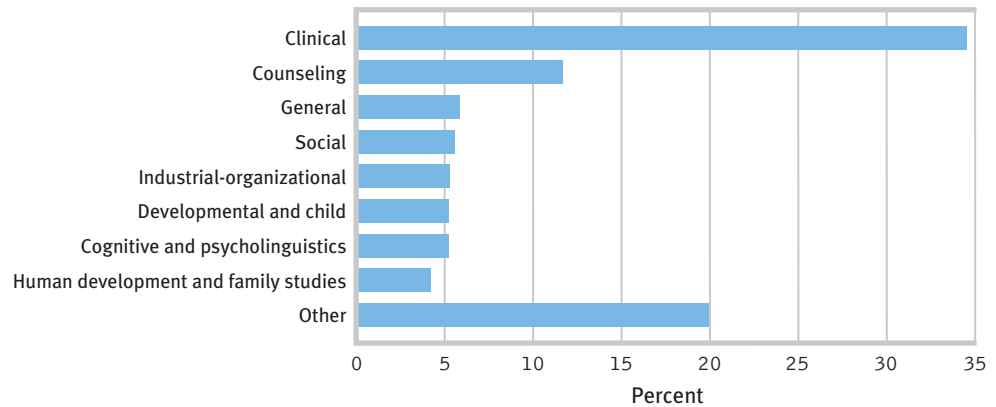

conduct research and also work in professional settings. If you pursue clinical and counseling psychology programs, you should expect at least a one-year internship in addition to the regular course work, clinical practice, and research.

FIGURE D.4 shows, by subfield, the Ph.D.s earned in the field of psychology in the United States in 2009, the most recent year for which these data are available (Mulvey, 2011). As you can see, clinical psychology is the most popular specialty area among people with doctorates in psychology.

Preparing Early for Graduate Study in Psychology

Competition for openings for advanced degree programs in psychology is keen. If you plan to go to graduate school after college, there are a number of things you can do in advance to maximize your chances of gaining admission to the school of your choice.

The first step is to take full advantage of your opportunities in high school. By enrolling in challenging elective courses and working hard to develop an academic skill set, you will have paved the way for success in college. Successful students also take the time to learn effective study skills and to establish disciplined study habits. Involve yourself in extracurricular activities, gain some experience in the world of work by taking on a part-time job, and look for opportunities to volunteer in your school and community. In addition to helping you grow as a person, becoming a well-rounded student with high standards helps you to earn scholarships and increases your chances of being accepted by the colleges and universities of particular interest to you.

During your first year on campus, continue to maximize opportunities and obtain the experience needed to gain admission to a competitive program. Kristy Arnold and Kelly Horrigan (2002) offer a number of suggestions to facilitate this process.

1. *Network.* Get to know the psychology department and its faculty members by attending activities and meetings. This strategy will be especially helpful when you apply to graduate school or for a professional position, because many applications require two to three letters of reference. Become involved in psychology clubs and in Psi Chi. These meetings connect students who have similar interests and expose them to a broader study of the field.
2. *Become actively involved in research as early as possible.* Start by doing simple tasks such as data entry and data collection, and over time you will be prepared to conduct your own research project under the supervision of a research mentor. To test your interest in academic careers and to build your skills for future study in psychology, consider applying for summer research positions through your university or through other organizations such as the American Psychological Association Summer Science Fellowship (SSF) program or the National Science Foundation Research Experiences for Undergraduates (REU) program.
3. *Volunteer or get a job in a psychology-related field.* Getting involved will show your willingness to apply psychological concepts to real-world settings. Further, it will showcase your ability to juggle a number of tasks successfully, such as work and school—an important skill for graduate school success.

Stephen Simpson/Getty Images

Membership benefits Members of the Psi Chi Honor Society, such as those meeting here, enjoy educational and professional benefits. They may attend special Psi Chi sessions at psychological conventions, apply for research grants in psychology or other academic awards, and read about research advances in the society's journal *Eye on Psi Chi*. (See www.psichi.org for more information.)

4. *Maintain good grades and prepare early for the GRE®.* Demonstrate the ability to do well in graduate school with successful completion of challenging courses, especially those related to your interests. (See the Close-up box in Module 2 and the final section in Module 33 for tips on how to do well in this and other courses, and how to improve your retention of the information you are learning.) In your junior year, you should begin studying for the Graduate Record Exam® (GRE®), the standardized test that applicants to graduate school must complete. Many graduate programs in psychology require both the General GRE® and the Psychology subject tests. If you start preparing early and maintain high grades, you will be ready for success in your graduate school application and study.

For More Information

How Can You Learn More About the Psychology Major and the Field of Psychology?

1. Talk with as many people as possible who have experience in the discipline of psychology. Your psychology teacher or school counselor may have some tips. Try to learn about opportunities to contact psychology majors, graduate students, instructors, and advisors, as well as other professionals who trained in psychology or work in the field.
2. Read books, such as those listed at the end of this appendix.
3. Take advantage of online resources. These resources can help you determine whether you would be well matched for a major and a career in psychology.
 - Watch online videos showcasing different careers in psychology, such as those at www.drkit.org/psychology/.
 - Play the Career Interest Game (www.career.missouri.edu/career-interest-game).
 - Get more information about specific jobs in psychology from the Bureau of Labor Statistics (www.tinyurl.com/PsychologyJobs), the Occupational Information Network (O*NET for short; www.onetcenter.org/), and the Occupational Outlook Handbook (OOH; www.bls.gov/ooh/).
 - Visit the websites of the American Psychological Association (www.apa.org) and Association for Psychological Science (www.psychologicalscience.org/). The APA has a lot to offer high school students who are interested in learning more about psychology. To learn more about membership at the high school level (which includes subscriptions to APA journals and mobile apps), visit www.apa.org/membership/hs-student/index.aspx. You can also become a member of the Psychology Student Network (www.apa.org/ed/precollege/psn/index.aspx).
 - Learn more about the honor societies in psychology, Psi Chi (www.psichi.org) and Psi Beta (www.psibeta.org).

What Are Some Books That Can Help You to Learn More About the Major, Careers, and Graduate School in Psychology?

- American Psychological Association (2007). *Getting in: A step-by-step plan for gaining admission to graduate school in psychology* (2nd ed.). Washington, DC: Author.
- American Psychological Association (2013). *Graduate study in psychology, 2014 edition*. Washington, DC: Author.
- Kracen, A. C., & Wallace, I. J. (Eds.) (2008). *Applying to graduate school in psychology: Advice from successful students and prominent psychologists*. Washington, DC: American Psychological Association.
- Kuther, T., & Morgan, R. D. (2010). *Careers in psychology: Opportunities in a changing world* (3rd ed.). Boston, MA: Wadsworth Cengage.
- Landrum, E. (2009). *Finding jobs with a psychology bachelor's degree: Expert advice for launching your career*. Washington, DC: American Psychological Association.

- Morgan, B., & Korschgen, A. (2009). *Majoring in psychology? Career options for psychology undergraduates* (4th ed.). Boston, MA: Pearson.
- Schultheiss, D. E. P. (2008). *Psychology as a major: Is it right for me and what can I do with my degree?* Washington, DC: American Psychological Association.
- Sternberg, R. (Ed.) (2006). *Career paths in psychology: Where your degree can take you* (2nd ed.). Washington, DC: American Psychological Association.
- Wegenek, A. R., & Buskist, W. (2010). *The insider's guide to the psychology major. Everything you need to know about the degree and the profession.* Washington, DC: American Psychological Association

Appendix E: Answers to Test Yourself Questions

Unit I

Psychology's History and Approaches

Module 1 Psychology's History

What event defined the founding of modern scientific psychology?

Answer: The founding of scientific psychology is often attributed to Wilhelm Wundt's opening of the University of Leipzig psychology laboratory in 1879. The new science of psychology was soon organized into different schools of thought, including *structuralism* (founded by Edward Bradford Titchener, using introspection to explore the elemental structure of the human mind) and *functionalism* (founded by William James, focusing on how mental and behavioral processes enable organisms to adapt, survive, and flourish). James also wrote an important psychology textbook, completed in 1890.

Module 2 Psychology's Big Issues and Approaches

What are psychology's major levels of analysis?

Answer: Psychology's three major levels of analysis are the biological, psychological, and social-cultural. The complementary insights of psychologists studying behavior and mental processes from the behavioral, biological, cognitive, evolutionary, humanistic, psychodynamic, and social-cultural perspectives offer a richer understanding than could usually be gained from any one viewpoint alone.

Module 3 Careers in Psychology

Name the subfields that focus on (a) people and their work environments, (b) how people change over the life span, (c) the human thinking involved in perceiving, remembering, speaking, and decision making, and (d) diagnosing and treating psychological disorders.

Answer: These subfields are (a) industrial-organizational psychology, (b) developmental psychology, (c) cognitive psychology, (d) clinical psychology.

Unit II

Research Methods: Thinking Critically With Psychological Science

Module 4 The Need for Psychological Science

How does the scientific attitude contribute to critical thinking?

Answer: The scientific attitude combines (1) *curiosity* about the world around us, (2) *skepticism* toward various claims and ideas, and

(3) *humility* about one's own understanding. Evaluating evidence, assessing conclusions, and examining our own assumptions are essential parts of critical thinking.

Module 5 The Scientific Method and Description

What are some strengths and weaknesses of the three different methods psychologists use to describe behavior—case studies, naturalistic observation, and surveys?

Answer: *Case studies* offer in-depth insights that may offer clues to what's true of others—or may, if the case is atypical, mislead. *Naturalistic observation* enables the study of behavior undisturbed by researchers. But the lack of control may leave cause and effect ambiguous. *Surveys* can accurately reveal the tendencies of large populations. But if the questions are leading, or if nonrandom samples are queried, the results can again mislead us.

Module 6 Correlation and Experimentation

Why, when testing a new drug to control blood pressure, would we learn more about its effectiveness from giving it to half of the participants in a group of 1000 than to all 1000 participants?

Answer: To determine the drug's effectiveness, we must compare its effect on those *randomly assigned* to receive it (the *experimental group*) with the other half of the participants (*control group*), who receive a *placebo*. If we gave the drug to all 1000 participants, we would have no way of knowing if the drug is serving as a placebo or if it is actually medically effective.

Module 7 Statistical Reasoning in Everyday Life

Can you solve this puzzle?

The registrar's office at the University of Michigan has found that usually about 100 students in Arts and Sciences have perfect grades at the end of their first term at the University. However, only about 10 to 15 students graduate with perfect grades. What do you think is the most likely explanation for the fact that there are more perfect grades after one term than at graduation (Jepson et al., 1983)?

Answer: Most students in the study came up with plausible causes for the drop in grades, such as, "Students tend to work harder at the beginning of their college careers than toward the end." Fewer than a third recognized the statistical phenomenon clearly at work: Averages based on fewer courses are more variable, which guarantees a greater number of extremely low and high grades at the end of the first term.

Module 8 Frequently Asked Questions About Psychology

How are human and animal research participants protected?

Answer: Animal protection legislation, laboratory regulation and inspection, and local ethics committees serve to protect human and animal welfare. At universities, Institutional Review Boards screen research proposals. Ethical principles developed by international psychological organizations urge researchers using human participants to obtain *informed consent*, to protect them from harm and discomfort, to treat their personal information confidentially, and to fully *debrief* all participants.

Unit III

Biological Bases of Behavior

Module 9 Biological Psychology and Neurotransmission

How do neurons communicate with one another?

Answer: A neuron fires when excitatory inputs exceed inhibitory inputs by a sufficient threshold. When the resulting impulse reaches the axon's end, it triggers the release of chemical messengers called *neurotransmitters*. After crossing a tiny space between one neuron's terminal branch and the next neuron's dendrite (the *synaptic gap*), these molecules chemically activate receptor sites on neighboring neurons.

Module 10 The Nervous and Endocrine Systems

How does information flow through your nervous system as you pick up a fork? Can you summarize this process?

Answer: Your central nervous system's hungry brain activates and guides the muscles of your arm and hand via your peripheral nervous system's motor neurons. As you pick up the fork, your brain processes the information from your sensory nervous system, enabling it to continue to guide the fork to your mouth. The functional circle starts with sensory input, continues with interneuron processing by the central nervous system, and finishes with motor output.

Why is the pituitary gland called the “master gland”?

Answer: Responding to signals from the hypothalamus, the pituitary releases hormones that trigger other endocrine glands to secrete hormones that in turn influence brain and behavior.

Module 11 Studying the Brain, and Older Brain Structures

Within what brain region would damage be most likely to disrupt your ability to skip rope? Your ability to sense tastes or sounds? In what brain region would damage perhaps leave you in a coma? Without the very breath and heartbeat of life?

Answer: These regions are, respectively, the *cerebellum*, the *thalamus*, the *reticular formation*, and the *medulla*. These questions assess your understanding of the essential functions of the lower-level brain areas.

Module 12 The Cerebral Cortex

Try moving your right hand in a circular motion, as if polishing a table. Then start your right foot doing the same motion, synchronized with your hand. Now reverse the right foot's

motion, but not the hand's. Finally, try moving the *left* foot opposite to the right hand.

1. Why is reversing the right foot's motion so hard?

2. Why is it easier to move the left foot opposite to the right hand?

Answer: 1. The right limbs' opposed activities interfere with each other because both are controlled by the same (left) side of your brain. 2. Opposite sides of your brain control your left and right limbs, so the reversed motion causes less interference.

Module 13 Brain Hemisphere Organization and the Biology of Consciousness

What are the mind's two tracks, and what is “dual processing”?

Answer: The human brain has separate conscious and unconscious tracks that process information simultaneously. In vision, for example, the visual action track normally guides our conscious visual processing, while the visual perception track normally operates unconsciously, enabling our quick recognition of objects.

Module 14 Behavior Genetics: Predicting Individual Differences

What is *heritability*?

Answer: *Heritability* is the proportion of variation among individuals that we can attribute to genes. *Note:* Heritability is *not* the extent to which an *individual's* traits are genetically determined. Rather, it is the extent to which variation *among* individuals is due to their differing genes. For any trait, heritability can vary, depending on the population and range of environments studied.

Module 15 Evolutionary Psychology: Understanding Human Nature

What are the three main criticisms of evolutionary psychology's explanations?

Answer: Critics of evolutionary psychology's explanations point out that (1) they start with an effect and work backward to propose an explanation; (2) unethical and immoral men could use such explanations to rationalize their behavior toward women; and (3) this explanation overlooks the effects of cultural expectations and socialization.

How does the biopsychosocial approach explain our individual development?

Answer: The biopsychosocial approach considers all the factors that influence our individual development: biological factors (including evolution, genes, hormones, and brains), psychological factors (including our experiences, beliefs, feelings, and expectations), and social-cultural factors (including parental and peer influences and cultural attitudes and norms).

Unit IV

Sensation and Perception

Module 16 Basic Principles of Sensation and Perception

Explain how Heather Sellers' experience of prosopagnosia illustrates the difference between sensation and perception.

Answer: Heather Sellers' *sensation* is normal, and her *perception* is nearly so, but her brain is lacking the functional area that helps us recognize a familiar human face. While her bottom-up physical sensory system receives and represents stimuli, a problem with her top-down mental process of organizing and interpreting sensory input results in her inability to recognize faces.

Module 17 Influences on Perception

What type of evidence shows that, indeed, "there is more to perception than meets the senses"?

Answer: We construct our perceptions based on both sensory input and—experiments show—on our assumptions, expectations, schemas, and perceptual sets, often influenced by the surrounding context.

What is the field of study that researches claims of extrasensory perception (ESP)?

Answer: It is called parapsychology, because it studies paranormal phenomena that are claimed to occur apart from any sensory input.

Module 18 Vision

What is the rapid sequence of events that occurs when you see and recognize a friend?

Answer: Light waves reflect off the person and travel into your eye, where the receptor cells in your retina convert the light waves' energy into neural impulses sent to your brain. Your brain then processes the subdimensions of this visual input—including color, depth, movement, and form—separately but simultaneously. It interprets this information based on previously stored information and your expectations into a conscious perception of your friend.

Module 19 Visual Organization and Interpretation

What do we mean when we say that, in perception, "the whole is greater than the sum of its parts"?

Answer: Gestalt psychologists used this saying to describe our perceptual tendency to organize clusters of sensations into meaningful forms or coherent groups.

Module 20 Hearing

What are the basic steps in transforming sound waves into perceived sound?

Answer: The *outer ear* collects sound waves, which are translated into mechanical waves by the *middle ear* and turned into fluid waves in the *inner ear*. The *auditory nerve* then translates the energy into electrical waves and sends them to the brain, which perceives and interprets the sound.

Module 21 The Other Senses

How does our system for sensing smell differ from our sensory systems for vision, touch, and taste?

Answer: We have two types of retinal receptors, four basic touch senses, and five taste sensations. But we have no basic smell receptors. Instead, different combinations of odor receptors send messages to the brain, enabling us to recognize some 10,000 discernible odors.

Unit V

States of Consciousness

Module 22 Understanding Consciousness and Hypnosis

When is the use of hypnosis potentially harmful, and when can hypnosis be used to help?

Answer: Hypnosis can be harmful if used to "hypnotically refresh" memories, which may plant false memories. But posthypnotic suggestions have helped alleviate some ailments, and hypnosis can also help control pain.

Module 23 Sleep Patterns and Sleep Theories

What five theories explain our need for sleep?

Answer: (1) Sleep has survival value. (2) Sleep helps restore and repair brain tissue. (3) During sleep we strengthen memory traces. (4) Sleep fuels creativity. (5) Sleep plays a role in the growth process.

Module 24 Sleep Deprivation, Sleep Disorders, and Dreams

Are you getting enough sleep? What might you ask yourself to answer this question?

Answer: You could start with the true/false questions in James Maas' sleep deprivation quiz in Table 24.1. Also, William Dement (1999, p. 73) has suggested considering these questions: "How often do you think about taking a quick snooze? How often do you rub your eyes and yawn during the day? How often do you feel like you really need some coffee?" Dement concluded that "each of these is a warning of a sleep debt that you ignore at your peril."

Module 25 Psychoactive Drugs

Why do tobacco companies try so hard to get customers hooked as teens?

Answer: Nicotine is powerfully addictive, expensive, and deadly. Those who start paving the neural pathways when young may find it very hard to stop using nicotine. As a result, tobacco companies may have lifelong customers.

Unit VI

Learning

Module 26 How We Learn and Classical Conditioning

As we develop, we learn cues that lead us to expect and prepare for good and bad events. We learn to repeat behaviors that bring rewards. And we watch others and learn. What do psychologists call these three types of learning?

Answer: Through *classical conditioning*, we learn cues that lead us to expect and prepare for good and bad events. Through *operant conditioning*, we learn to repeat behaviors that bring rewards. Through *cognitive learning*, we watch others and learn.

In slasher movies, sexually arousing images of women are sometimes paired with violence against women. Based on classical conditioning principles, what might be an effect of this pairing?

Answer: If viewing an attractive nude or semi-nude woman (a US) elicits sexual arousal (a UR), then pairing the US with a new stimulus (violence against women) could turn the violence into a conditioned stimulus (CS) that also becomes sexually arousing, a conditioned response (CR).

Module 27 Operant Conditioning

Fill in the three blanks below with one of the following terms: negative reinforcement (NR), positive punishment (PP), and negative punishment (NP). The first answer, positive reinforcement (PR), is provided for you.

Type of Stimulus	Give It	Take It Away
Desired (for example, a teen's use of the car):	1. PR	2. NP
Undesired/aversive (for example, an insult):	3. PP	4. NR

Module 28 Operant Conditioning's Applications, and Comparison to Classical Conditioning

Salivating in response to a tone paired with food is a(n) _____ behavior; pressing a bar to obtain food is a(n) _____ behavior.

Answer: Salivating in response to a tone paired with food is an example of respondent behavior, while pressing a bar to obtain food is an example of operant behavior.

Module 29 Biology, Cognition, and Learning

When faced with a situation over which you feel you have no sense of control, is it most effective to use emotion- or problem-focused coping? Why?

Answer: It is better to use emotion-focused coping because it helps to alleviate stress and attends to our emotional needs in situations that we feel we cannot change. Emotion-focused coping (such as hanging out with friends before a big test), can become maladaptive, however, when a problem-focused strategy (such as studying) would have been more effective.

Module 30 Learning by Observation

Jason's parents and older friends all smoke, but they advise him not to. Juan's parents and friends don't smoke, but they say nothing to deter him from doing so. Will Jason or Juan be more likely to start smoking?

Answer: Jason may be more likely to smoke, because observational learning studies suggest that children tend to do as others do and say what they say.

Unit VII Cognition

Module 31 Studying and Building Memories

Memory includes (in alphabetical order) long-term memory, sensory memory, and working/short-term memory. What's the correct order of these three memory stages?

Answer: Sensory memory, working/short-term memory, long-term memory.

What would be the most effective strategy to learn and retain a list of names of key historical figures for a week? For a year?

Answer: For a week: Make the names personally meaningful. For a year: Take advantage of the spacing effect by spreading your learning over several months.

Module 32 Memory Storage and Retrieval

Your friend tells you that her father experienced brain damage in an accident. She wonders if psychology can explain why he can still play checkers very well but has a hard time holding a sensible conversation. What can you tell her?

Answer: Our *explicit* (declarative) memories differ from our *implicit* (nondeclarative) memories of skills and procedures, such as playing checkers. Our implicit memories are processed by more ancient brain areas, which apparently escaped damage during the accident.

You have just watched a movie that includes a chocolate factory. After the chocolate factory is out of mind, you nevertheless feel a strange urge for a chocolate bar. How do you explain this in terms of priming?

Answer: *Priming* is the activation (often without our awareness) of associations. Seeing a chocolate factory in a movie, for example, might temporarily predispose you to crave a chocolate treat. Although you might not consciously remember the chocolate factory, it may prime how you interpret or recall events.

Module 33 Forgetting, Memory Construction, and Memory Improvement

Can you offer examples of proactive and retroactive interference?

Answer: *Proactive* (forward-acting) *interference* occurs when earlier learning disrupts your recall of a later experience. Proactive interference has occurred if learning names of new classmates in your first class makes it more difficult to learn the new names in your second class or if the combination of last year's lock makes it difficult to learn the new combination for this year's lock. *Retroactive interference* has occurred if those new classmate's names in the second class, or that new combination, interferes with your memory of the first class student names or last year's lock.

How would source amnesia affect us if we were to remember all of our waking experiences as well as all of our dreams?

Answer: Real experiences would be confused with those we dreamed. When meeting someone, we might therefore be unsure whether we were reacting to something they previously did or to something we dreamed they did. William Dement (1999, p. 298) thinks this “would put a great burden on your sanity. . . . I truly believe that the wall of memory is a blessed protection.”

What are the recommended memory strategies you just read about? (One advised rehearsing to-be-remembered material. What were the others?)

Answer: Study repeatedly to boost long-term recall, and schedule spaced (not crammed) study times. Spend more time rehearsing or actively thinking about the material. Make the material personally meaningful, with well-organized and vivid associations. Refresh your memory by returning to contexts and moods to activate retrieval cues. Use mnemonic devices. Minimize interference. Plan for a complete night’s sleep. Test yourself repeatedly—retrieval practice is a proven retention strategy.

Module 34 Thinking, Concepts, and Creativity

According to Robert Sternberg, what are the five components of creativity?

Answer: Sternberg identified expertise, imaginative thinking skills, a venturesome personality, intrinsic motivation, and a creative environment as the five components of creativity.

Module 35 Solving Problems and Making Decisions

The availability heuristic is a quick-and-easy but sometimes misleading guide to judging reality. What is the availability heuristic?

Answer: The *availability heuristic* is our tendency to judge the likelihood of an event by how easily we can recall instances of it. Like all heuristics, this guide is efficient. But it can mislead, as it does when we attempt to judge various risks (for example, of plane travel).

Module 36 Thinking and Language

If children are not yet speaking, is there any reason to think they would benefit from parents and other caregivers reading to them?

Answer: Indeed there is, because well before age 1 children are learning to detect words among the stream of spoken sounds and to discern grammatical rules. Before age 1, they also are babbling with the phonemes of their own language. More than many parents realize, their infants are soaking up language. As researcher Peter Jusczyk reminds us, “Little ears are listening.”

To say that “words are the mother of ideas” assumes the truth of what concept?

Answer: This phrase supports the *linguistic determinism hypothesis*, which asserts that language determines thought. Research indicates that this position is too extreme, but language does *influence* what we perceive and think.

Unit VIII

Motivation, Emotion, and Stress

Module 37 Motivational Concepts

While on a long road trip, you suddenly feel very hungry. You see a diner that looks pretty deserted and creepy, but you are *really* hungry, so you stop anyway. What motivational perspective would most easily explain this behavior, and why?

Answer: *Drive-reduction theory*—the idea that physical needs create an aroused state that drives us to reduce the need—helps explain your behavior.

Module 38 Hunger Motivation

You’ve skipped lunch to meet with your guidance counselor, so you haven’t eaten anything in eight hours. As your favorite dish is placed in front of you, your mouth waters. Even imagining this may set your mouth to watering. What triggers this anticipatory salivation?

Answer: You, like Pavlov’s dogs, have learned through *classical conditioning* to respond to the cues—the sight and aroma—that signal the food about to enter your mouth. Both *physiological cues* (eight hours of deprivation have left you with low blood sugar) and *psychological cues* (the anticipation of the tasty meal) have heightened your experienced hunger.

Module 39 Sexual Motivation

How might the evolutionary perspective, drive-reduction theory, and arousal theory explain our sexual motivation?

Answer: *Evolutionary perspective:* Those motivated to have sex were more likely to leave descendants—us—than were others who lacked sexual motivation. *Drive-reduction theory:* Hormonal influences create a driven (physiologically aroused) state that compels us to reduce the drive. *Arousal theory:* People sometimes *seek* the pleasure and stimulation of arousal.

Module 40 Social Motivation: Affiliation Needs

How might the evolutionary perspective, drive-reduction theory, and arousal theory explain our affiliation needs?

Answer: *Evolutionary perspective:* Our ancestors hunted and survived threats as group-dwelling creatures, finding food and safety in numbers. As their descendants, we therefore are disposed to live in groups, connected to supportive others. *Drive-reduction theory:* Being threatened and afraid drives us to find safety in the company of others (thus reducing our aroused state). *Arousal theory:* We welcome optimal levels of arousal, and the presence of others is arousing.

Module 41 Theories and Physiology of Emotion

Christine is holding her 8-month-old baby when a fierce dog appears out of nowhere and, with teeth bared, leaps for the baby's face. Christine immediately ducks for cover to protect the baby, screams at the dog, then notices that her heart is banging in her chest and she's broken out in a cold sweat. How would the James-Lange, Cannon-Bard, and two-factor theories explain Christine's emotional reaction?

Answer: *James-Lange theory:* Christine's emotional reaction consists of her awareness of her physiological responses to the dog attack. *Cannon-Bard theory:* Christine's fear experience happened simultaneously with her physiological arousal. Schachter and Singer's *two-factor theory:* Christine's emotional reaction stemmed from her interpreting and labeling the arousal.

How do the two divisions of the autonomic nervous system affect our emotional responses?

Answer: The *sympathetic division* of the ANS arouses us for more intense experiences of emotion, pumping out the stress hormones epinephrine and norepinephrine to prepare our body for fight or flight. The *parasympathetic division* of the ANS takes over when a crisis passes, restoring our body to a calm physiological and emotional state.

Module 42 Expressed Emotion

Who tends to express more emotion—men or women? How do we know the answer to that question?

Answer: Women tend to surpass men not only as emotion detectors but also at expressing certain emotions (though men have slightly surpassed women in conveying anger). Researchers discovered this by showing people brief, silent clips of men's and women's faces expressing various emotions and by observing who is most skilled at reading and sending emotions.

Module 43 Stress and Health

What two processes happen simultaneously when our stress response system is activated? What happens if the stress is continuous?

Answer: When alerted to a negative, uncontrollable event, our sympathetic nervous system arouses us. Heart rate and respiration increase. Blood is diverted from digestion to the skeletal muscles. The body releases sugar and fat. All this prepares the body for the fight-or-flight-response.

Module 44 Stress and Illness

Which component of the Type A personality has been linked most closely to coronary heart disease?

Answer: Feeling angry and negative much of the time has been most closely tied to heart disease.

Unit IX

Developmental Psychology

Module 45 Developmental Issues, Prenatal Development, and the Newborn

What findings in psychology support the concept of stages in development and the idea of stability in personality across the life span? What findings challenge these ideas?

Answer: The idea of stages in development is supported by the work of Piaget (cognitive development), Kohlberg (moral development), and Erikson (psychosocial development), but it is challenged by findings that suggest change is more gradual and less culturally universal than these theorists supposed. Some personality traits, such as temperament, do exhibit remarkable stability across many years. But we do change in other ways, such as in our social attitudes, especially during life's early years.

Your friend's older sister—a regular drinker—hopes to become pregnant soon and has stopped drinking. Why is this a good idea? What negative effects might alcohol consumed during pregnancy have on a developing fetus?

Answer: There is no known safe amount of alcohol during pregnancy, so your friend's older sister is wise to quit drinking before becoming pregnant. Harmful effects may occur even before a woman knows she is pregnant. If a woman drinks persistently and heavily during her pregnancy, the fetus will be at risk for severe physical and cognitive impairments (such as occurs with *fetal alcohol syndrome*).

Module 46 Infancy and Childhood: Physical Development

What is the biological growth process that explains why most children begin walking by about 12 to 15 months?

Answer: This process is called *maturation*, which enables orderly changes in behavior, relatively unchanged by experience.

Module 47 Infancy and Childhood: Cognitive Development

Use Piaget's first three stages of cognitive development to explain why children are not just miniature adults in the way they think.

Answer: Infants in the *sensorimotor stage* tend to be focused only on their own perceptions of the world and may, for example, be unaware that objects continue to exist when unseen. A *preoperational* child is still egocentric and incapable of appreciating simple logic, such as the reversibility of operations. A preteen in the *concrete operational stage* is beginning to think logically about concrete events but not about abstract concepts.

Module 48 Infancy and Childhood: Social Development

What distinguishes imprinting from attachment?

Answer: Attachment is the normal process by which we form emotional ties with important others. Imprinting occurs in certain animals that have a critical period very early in their development during which they must form their attachments, and they do so in an inflexible manner.

Module 49 Gender Development

What are gender roles, and what do their variations tell us about our human capacity for learning and adaptation?

Answer: *Gender roles* are sets of expected behaviors for females and for males. Gender roles vary widely in different cultures, which is proof that we are very capable of learning and adapting to the social demands of different environments.

Module 50 Parents, Peers, and Early Experiences

To predict whether a teenager smokes, ask how many of the teen's friends smoke. One explanation for this correlation is peer influence. What's another?

Answer: There may also be a *selection effect*. Adolescents tend to select similar others and sort themselves into like-minded groups—the jocks, the geeks, the druggies, and so forth. Those who smoke may similarly seek out other teenagers who also smoke.

Module 51 Adolescence: Physical and Cognitive Development

Describe Kohlberg's three levels of moral reasoning.

Answer: Preconventional morality focuses on upholding laws and social rules, conventional morality focuses on self-interest, and postconventional morality focuses on self-defined ethical principles.

Module 52 Adolescence: Social Development and Emerging Adulthood

How has the transition from childhood to adulthood changed in Western cultures in the last century or so?

Answer: In little more than a century, the gap between puberty and adult independence has widened from about 7 years to about 12 years. This longer adolescence gives us a chance to grow up a bit more before facing the “real world,” but it also comes with its share of stressors, as sexually mature teens must wait many years before achieving true independence. In Western nations, this has led to a postadolescent, not-yet-settled phase of life known as *emerging adulthood*.

Module 53 Sexual Development

What factors have been found to predict sexual restraint among teens?

Answer: Teen sexual restraint is found more often among teens with high intelligence, religious engagement, family environments with a father presence, and among those who participate in service learning programs.

Module 54 Adulthood: Physical, Cognitive, and Social Development

Research has shown that living together before marriage predicts an increased likelihood of future divorce. Can you imagine two possible explanations for this correlation?

Answer: William Axinn and Arland Thornton (1992) have reported data supporting two explanations. (1) The first explanation is an ex-

ample of a *selection effect*—our tendency to seek out others who are similar to us. Cohabitation attracts people who are more open to terminating unsatisfying relationships. People who cohabit bring a more individualistic ethic to marriage, are more likely to see close relationships as temporary and fragile, are more accepting of divorce, and are about three times more likely after marriage to have an affair (Forste & Tanfer, 1996). (2) Axinn and Thornton's second explanation illustrates the *causal effect* of the experience of cohabitation. Over time, those who cohabit tend to become more approving of dissolving an unfulfilling union. This divorce-accepting attitude increases the odds of later divorce.

Unit X

Personality

Module 55 Freud's Psychoanalytic Perspective: Exploring the Unconscious

How does today's psychological science assess Freud's theory?

Answer: It was Freud who drew our attention to the unconscious and the irrational, to our self-protective defenses, to the importance of human sexuality, and to the tension between our biological impulses and our social well-being. But both Freud's admirers and his critics agree that recent research contradicts many of his specific ideas. It does not support *repression* or Freud's view of the unconscious (but instead views the unconscious as part of our two-track mind). Other modern research has led today's psychologists to see our development as lifelong, not fixed in childhood, and dreams and slips of the tongue not to illustrate urges and conflicts as Freud believed. It's also important to recognize, from a psychological science perspective, that Freudian theory does not enable predictions, and it tends to explain things after the fact.

Module 56 Psychodynamic Theories and Modern Views of the Unconscious

What methods have been used by psychodynamic clinicians to assess unconscious processes?

Answer: Projective tests, such as the *Thematic Apperception Test (TAT)* and the *Rorschach inkblot test*, are personality assessment tools psychodynamic clinicians have used with the aim of assessing unconscious processes. Critics say that projective tests such as the Rorschach have little validity and are not reliable.

Module 57 Humanistic Theories

What does it mean to be “empathic”? To be “self-actualized”?

Answer: To be *empathic* is to share and mirror another person's feelings. Carl Rogers believed that people nurture growth in others by being empathic. Abraham Maslow viewed *self-actualization*—the motivation to fulfill one's potential—as one of the ultimate psychological needs that arises after our physical needs are met. (The other ultimate psychological need is *self-transcendence*—meaning, purpose, and communion beyond the self.)

Module 58 Trait Theories

What is the person-situation controversy?

Answer: The *person-situation controversy* is the question of whether personality traits are consistent over time and across situations. Traits do tend to be consistent, though specific behaviors may vary with time and place.

Module 59 Social-Cognitive Theories and Exploring the Self

What do social-cognitive psychologists consider the best way to predict a person's future behavior?

Answer: Examining a person's past behavior patterns in similar situations is the best way to predict that person's future behavior.

In a 1997 Gallup poll, White Americans estimated 44 percent of their fellow White Americans to be high in prejudice (scoring them 5 or higher on a 10-point scale). How many rated themselves similarly high in prejudice? Just 14 percent. What phenomenon does this illustrate?

Answer: This illustrates the general tendency to see ourselves as superior to the average other, which is an example of *self-serving bias*.

How do individualist and collectivist cultures differ?

Answer: A culture that favors *individualism* gives priority to personal goals over group goals; people in that culture will tend to define their identity in terms of their own personal attributes. A culture that favors *collectivism* gives priority to group goals over individual goals; people in collectivist cultures tend to define their identity in terms of group identifications. Cultures vary in the extent to which they favor individualism or collectivism.

Unit XI

Testing and Individual Differences

Module 60 Introduction to Intelligence

Joseph, a Harvard Law School student, has a straight-A average, writes for the *Harvard Law Review*, and will clerk for a Supreme Court justice next year. His grandmother, Judith, is very proud of him, saying that he is way more intelligent than she ever was. But Joseph is also very proud of Judith: As a young woman, she was imprisoned by the Nazis. When the war ended, she walked out of Germany, contacted an agency helping refugees, and began a new life in the United States as an assistant chef in her cousin's restaurant. According to the definition of *intelligence* in this module, is Joseph the only intelligent person in this story? Why or why not?

Answer: Joseph is not the only intelligent person in this story. *Intelligence* is the ability to learn from experience, solve problems, and use knowledge to adapt to new situations. Judith certainly demonstrates this quality as well, given all that she has accomplished.

Module 61 Assessing Intelligence

What was the purpose of Binet's pioneering intelligence test?

Answer: Binet's original test and those built upon it were designed to predict school achievement. Binet hoped that by determining a child's *mental age*, or the age that typically corresponds to level

of performance, he could help children be placed appropriately in school classrooms with others of similar abilities.

Module 62 The Dynamics of Intelligence

The Smiths have enrolled their 2-year-old son in a special program that promises to assess his IQ and, if he places in the top 5 percent of test-takers, to create a plan that will guarantee his admission to a top university at age 18. Why is this endeavor of questionable value?

Answer: This is a waste of money at best. First, IQ tests given before age 3 are only modestly reliable predictors of adult intelligence. Second, admission to a top university depends on more than simple IQ. Third, there are no known training programs that could guarantee this result. The Smiths would do better to read to their child, which predicts early reading and love of reading.

Module 63 Studying Genetic and Environmental Influences on Intelligence

As society succeeds in creating equality of opportunity, it will also increase the heritability of ability. The heritability of intelligence scores will be greater in a society marked by equal opportunity than in a society of peasants and aristocrats. Why?

Answer: Perfect environmental equality would create 100 percent heritability—because genes alone would account for any remaining human differences.

Module 64 Group Differences and the Question of Bias

What is the difference between a test that is biased culturally, and a test that is biased in terms of its validity?

Answer: A test may be *culturally* biased if higher scores are achieved by those with certain cultural experiences. That same test may not be biased in terms of *validity* if it predicts what it is supposed to predict. For example, the SAT® may be culturally biased in favor of those with experience in the U.S. school system, but it does still accurately predict U.S. college success.

Unit XII

Abnormal Behavior

Module 65 Introduction to Psychological Disorders

What is the biopsychosocial approach, and why is it important in our understanding of psychological disorders?

Answer: Biological, psychological, and social-cultural influences combine to produce psychological disorders. This broad perspective helps us understand that our well-being is affected by our genes, brain functioning, inner thoughts and feelings, and the influence of our social and cultural environment.

Module 66 Anxiety Disorders, Obsessive-Compulsive Disorder, and Posttraumatic Stress Disorder

How do generalized anxiety disorder, panic disorder, phobias, obsessive-compulsive disorder, and posttraumatic stress disorder differ?

Answer: *Generalized anxiety disorder* is unfocused tension, apprehension, and arousal. *Panic disorder* is marked by unpredictable periods of terror and intense dread accompanied by frightening physical sensations. Those with *phobias* focus anxiety on specific feared objects or situations. People suffering *obsessive-compulsive disorder* express anxiety through unwanted repetitive thoughts (obsessions) or actions (compulsions). In *posttraumatic stress disorder (PTSD)*, anxiety may be accompanied by recurring memories and nightmares, social withdrawal, and insomnia for periods of four or more weeks after a traumatic event.

Module 67 Mood Disorders

What is the most common psychological disorder? What is the disorder for which people most often seek treatment?

Answer: Phobias are the most common psychological disorders, but the disorder for which people most often seek treatment is depression.

Module 68 Schizophrenia

How do researchers believe that biological and environmental factors interact in the onset of schizophrenia?

Answer: *Schizophrenia* has powerful biological roots, as evidenced by findings that those suffering from schizophrenia have increased receptors for the neurotransmitter dopamine (which may intensify the positive symptoms of schizophrenia); abnormal activity in the frontal lobes, thalamus, and amygdala; and such brain abnormalities as fluid-filled cerebral cavities. Malfunctions in multiple brain regions and their connections apparently interact to produce the symptoms of schizophrenia. Yet environment must play some role, because identical twins don't always share the expression of this disorder, and there is increasing evidence that a virus suffered by the mother during midpregnancy can contribute to that baby's later developing schizophrenia.

Module 69 Other Disorders

What does *somatic* mean?

Answer: Somatic symptoms are bodily symptoms. A *somatic disorder* is one in which symptoms take a somatic (bodily) form without apparent physical cause.

The psychodynamic and learning perspectives agree that dissociative identity disorder symptoms are ways of dealing with anxiety. How do their explanations differ?

Answer: The psychodynamic explanation of DID symptoms is that they are defenses against anxiety generated by unacceptable urges. The learning perspective attempts to explain these symptoms as behaviors that have been reinforced by relieving anxiety in the past. Others attempt to explain DID symptoms as detachment resulting from horrific experiences, such as childhood abuse.

What contribution do genes make to the development of antisocial personality disorder?

Answer: *Antisocial personality disorder*—in which a person exhibits a lack of conscience for wrongdoing—seems to have a strong

genetic component. Twin and adoption studies show that biological relatives of people with this disorder are at increased risk for antisocial behavior. But the tendency to be fearless, when combined with a sense of social responsibility, can lead to heroism, adventurism, or athletic success. Genetic predispositions may interact with the environment to produce the altered brain activity associated with antisocial personality disorder.

Unit XIII

Treatment of Abnormal Behavior

Module 70 Introduction to Therapy, and Psychodynamic and Humanistic Therapies

In psychoanalysis, what does it mean when we refer to transference, resistance, and interpretation?

Answer: In psychoanalysis, patients may experience strong feelings for their analyst, which is called *transference*. Patients are said to demonstrate anxiety when they put up mental blocks around sensitive memories—showing *resistance*. The analyst will attempt to offer insight into the underlying anxiety by offering an *interpretation* of the mental blocks.

Module 71 Behavior, Cognitive, and Group Therapies

What is the major distinction between the underlying assumptions in insight therapies and in behavior therapies?

Answer: The *insight therapies*—psychodynamic and humanistic therapies—seek to relieve problems by providing an understanding of their origins. *Behavior therapies* assume the problem behavior is the problem and treat it directly, paying less attention to its origins.

Module 72 Evaluating Psychotherapies and Prevention Strategies

What is the difference between preventive mental health and psychological or biomedical therapy?

Answer: Psychological and biomedical therapies attempt to relieve people's suffering from psychological disorders. Preventive mental health attempts to prevent suffering by identifying and eliminating the conditions that cause disorders, and by building individuals' *resilience*.

Module 73 The Biomedical Therapies

How do researchers evaluate the effectiveness of particular drug therapies?

Answer: Ideally, researchers assign people to treatment and no-treatment conditions to see if those who receive the drug therapy improve more than those who don't. Double-blind controlled studies are most effective. If neither the therapist nor the client knows which participants have received the drug treatment, then any difference between the treated and untreated groups will reflect the treatment's actual effect.

Unit XIV

Social Psychology

Module 74 Attribution, Attitudes, and Actions

Driving to school one snowy day, Marco narrowly misses a car that slides through a red light. “Slow down! What a terrible driver,” he thinks to himself. Moments later, Marco himself slides through an intersection and yelps, “Wow! These roads are awful. The city plows need to get out here.” What social psychology principle has Marco just demonstrated? Explain.

Answer: By attributing the other person’s behavior to the person (“What a terrible driver.”) and his own, similar behavior to the situation (“These roads are awful.”), Marco has exhibited the *fundamental attribution error*.

Module 75 Conformity and Obedience

What types of situations have researchers found to be most likely to encourage obedience in participants?

Answer: The Milgram studies showed that people were most likely to follow orders when the experimenter was nearby and was a legitimate authority figure, the victim was not nearby, and there were no models for defiance.

Module 76 Group Behavior

You are organizing a Town Hall–style meeting of fiercely competitive political candidates. To add to the fun, friends have suggested handing out masks of the candidates’ faces for supporters to wear. What phenomenon might these masks engage?

Answer: The anonymity provided by the masks, combined with the arousal of the contentious setting, might create *deindividuation* (lessened self-awareness and self-restraint).

Module 77 Prejudice and Discrimination

What is the difference between prejudice and discrimination?

Answer: Prejudice is an unjustifiable and usually negative *attitude* toward a group and its members, while unjustifiable negative *behavior* is discrimination.

Module 78 Aggression

What psychological, biological, and social-cultural influences interact to produce aggressive behaviors?

Answer: Our biology (our genes, neural systems, and biochemistry—including testosterone and alcohol levels) influences our tendencies to be aggressive. Psychological factors (such as frustration, previous rewards for aggressive acts, and observation of others’ aggression) can trigger any aggressive tendencies we may have. Social influences, such as exposure to violent media, and cultural influences, such as whether we’ve grown up in a “culture of honor” or had a father-absent home, can also affect our aggressive responses.

Module 79 Attraction

How does being physically attractive influence others’ perceptions?

Answer: Being physically attractive tends to elicit positive first impressions. People tend to assume that attractive people are healthier, happier, and more socially skilled than others are.

Module 80 Altruism, Conflict, and Peacemaking

Why didn’t anybody help Kitty Genovese? What social relations principle did this incident illustrate?

Answer: In the presence of others, an individual is less likely to notice a situation, correctly interpret it as an emergency, and then take responsibility for offering help. The Kitty Genovese case demonstrated this *bystander effect*, as each witness assumed many others were also aware of the event.

Enrichment Modules

Module 81 Influences on Drug Use

Studies have found that people who begin drinking in their early teens are much more likely to exhibit alcohol use disorder than those who begin at age 21 or after. What possible explanations might there be for this correlation between early use and later abuse?

Answer: Possible explanations include (a) a biological predisposition to both early use and later abuse, (b) brain changes and taste preferences induced by early use, and (c) enduring habits, attitudes, activities, or peer relationships that foster alcohol misuse.

Module 82 Psychology at Work

A human resources director explains to you that “I don’t bother with tests or references. It’s all about the interview.” Based on I/O psychology research, what concerns does this raise?

Answer: (1) Interviewers may presume people are what they seem to be in interviews. (2) Interviewers’ preconceptions and moods color how they perceive interviewees’ responses. (3) Interviewers tend to track the successful careers of those they hire, not the successful careers of those they reject. (4) Interviews tend to disclose prospective workers’ good intentions, not their habitual behaviors.

What are the two basic types of leadership, and how do the most effective managers employ these leadership strategies?

Answer: *Task leadership* is goal-oriented. Managers using this style set standards, organize work, and focus attention on goals. *Social leadership* is group-oriented. Managers using this style build teamwork, mediate conflict, and offer support. Research indicates that effective managers exhibit both task and social leadership, depending on the situation and the person.

One of the ways human factors psychologists seek to reduce users' frustration and to improve safety is by watching out for the *curse of knowledge*. What exactly is this tendency?

Answer: The *curse of knowledge* is the tendency for engineers and other designers to assume falsely that others share their knowledge—that what's clear to them will be similarly clear to others.

Module 83 Experienced Emotion: Anger and Happiness

What things do (and do not) predict self-reported happiness?

Answer: People's age, sex, and income give only modest clues to their happiness. Their personality traits, close relationships, "flow" in work and leisure, and religious faith do provide clues.

Module 84 Human Flourishing

Those who frequently attend religious services live longer, on average, than those who attend infrequently or not at all. What type of research finding is this, and what explanations might it have?

Answer: This is a correlational finding—frequent attendance at religious services is associated with (and predicts) health and

longevity. But this is not a cause-effect statement. Longevity may be associated with religiosity because women (who tend to live longer than men) attend services more regularly, or because people in poor health are not able to attend services. But even controlling for these factors, the relationship remains, which indicates that the connection could reflect the healthy behaviors, stress-reducing social support, relaxed meditative state, optimistic outlook, and enhanced well-being often experienced by religiously active people.

Module 85 Animal Thinking and Language

If your dog barks at a stranger at the front door, does this qualify as language? What if the dog yips in a telltale way to let you know she needs to go out?

Answer: These are definitely communications. But if language consists of words and the grammatical rules we use to combine them to communicate meaning, few scientists would label a dog's barking and yipping as language.

This page intentionally left blank

Glossary

absolute threshold the minimum stimulation needed to detect a particular stimulus 50 percent of the time. (p. 156)

accommodation (1) in sensation and perception, the process by which the eye's lens changes shape to focus near or far objects on the retina. (p. 172) (2) in developmental psychology, adapting our current understandings (schemas) to incorporate new information. (p. 477)

achievement motivation a desire for significant accomplishment; for mastery of skills or ideas; for control; and for attaining a high standard. (p. 834)

achievement test a test designed to assess what a person has learned. (p. 619)

acquisition in classical conditioning, the initial stage, when one links a neutral stimulus and an unconditioned stimulus so that the neutral stimulus begins triggering the conditioned response. In operant conditioning, the strengthening of a reinforced response. (p. 268)

action potential a neural impulse; a brief electrical charge that travels down an axon. (p. 78)

active listening empathic listening in which the listener echoes, restates, and clarifies. A feature of Rogers' client-centered therapy. (p. 712)

adaptation-level phenomenon our tendency to form judgments (of sounds, of lights, of income) relative to a neutral level defined by our prior experience. (p. 851)

addiction compulsive craving of drugs or certain behaviors (such as gambling) despite known adverse consequences. (p. 247)

adolescence the transition period from childhood to adulthood, extending from puberty to independence. (p. 513)

adrenal [ah-DREEN-el] **glands** a pair of endocrine glands that sit just above the kidneys and secrete hormones (epinephrine and norepinephrine) that help arouse the body in times of stress. (p. 91)

aerobic exercise sustained exercise that increases heart and lung fitness; may also alleviate depression and anxiety. (p. 859)

aggression any physical or verbal behavior intended to hurt or destroy. (pp. 501, 789)

agonist a molecule that, by binding to a receptor site, stimulates a response. (p. 82)

agoraphobia fear or avoidance of situations, such as crowds or wide-open places, where one has felt loss of control and panic. (p. 663)

AIDS (acquired immune deficiency syndrome) a life-threatening, sexually transmitted infection caused by the *human immunodeficiency virus* (HIV). AIDS depletes the immune system, leaving the person vulnerable to infections. (p. 529)

alcohol use disorder (popularly known as *alcoholism*). Alcohol use marked by tolerance, withdrawal, and a drive to continue problematic use. (p. 249)

algorithm a methodical, logical rule or procedure that guarantees solving a particular problem. Contrasts with the usually speedier—but also more error-prone—use of *heuristics*. (p. 361)

all-or-none response a neuron's reaction of either firing (with a full-strength response) or not firing. (p. 80)

alpha waves the relatively slow brain waves of a relaxed, awake state. (p. 227)

altruism unselfish regard for the welfare of others. (p. 807)

amphetamines drugs that stimulate neural activity, causing speeded-up body functions and associated energy and mood changes. (p. 250)

amygdala [uh-MIG-duh-la] two lima-bean-sized neural clusters in the limbic system; linked to emotion. (p. 99)

anorexia nervosa an eating disorder in which a person (usually an adolescent female) maintains a starvation diet despite being significantly (15 percent or more) underweight. (p. 697)

antagonist a molecule that, by binding to a receptor site, inhibits or blocks a response. (pp. 83, 342)

anterograde amnesia an inability to form new memories. (p. 342)

antianxiety drugs drugs used to control anxiety and agitation. (p. 741)

antidepressant drugs drugs used to treat depression, anxiety disorders, obsessive-compulsive disorder, and posttraumatic stress disorder. (Several widely used antidepressant drugs are *selective serotonin reuptake inhibitors*—SSRIs.) (p. 741)

antipsychotic drugs drugs used to treat schizophrenia and other forms of severe thought disorder. (p. 741)

antisocial personality disorder a personality disorder in which a person (usually a man) exhibits a lack of conscience for wrongdoing, even toward friends and family members. May be aggressive and ruthless or a clever con artist. (p. 699)

anxiety disorders psychological disorders characterized by distressing, persistent anxiety or maladaptive behaviors that reduce anxiety. (p. 661)

aphasia impairment of language, usually caused by left-hemisphere damage either to Broca's area (impairing speaking) or to Wernicke's area (impairing understanding). (p. 377)

applied research scientific study that aims to solve practical problems. (p. 14)

aptitude test a test designed to predict a person's future performance; aptitude is the capacity to learn. (p. 619)

assimilation interpreting our new experiences in terms of our existing schemas. (p. 477)

association areas areas of the cerebral cortex that are not involved in primary motor or sensory functions; rather, they are involved in higher mental functions such as learning, remembering, thinking, and speaking. (p. 109)

associative learning learning that certain events occur together. The events may be two stimuli (as in classical conditioning) or a response and its consequences (as in operant conditioning). (p. 264)

attachment an emotional tie with another person; shown in young children by their seeking closeness to the caregiver and showing distress on separation. (p. 488)

attention-deficit/hyperactivity disorder (ADHD) a psychological disorder marked by the appearance by age 7 of one or more of three key symptoms: extreme inattention, hyperactivity, and impulsivity. (p. 652)

attitude feelings, often influenced by our beliefs, that predispose us to respond in a particular way to objects, people, and events. (p. 756)

attribution theory the theory that we explain someone's behavior by crediting either the situation or the person's disposition. (p. 754)

audition the sense or act of hearing. (p. 194)

autism spectrum disorder (ASD) a disorder that appears in childhood and is marked by significant deficiencies in communication and social interaction, and by rigidly fixated interests and repetitive behaviors. (p. 481)

automatic processing unconscious encoding of incidental information, such as space, time, and frequency, and of well-learned information, such as word meanings. (p. 320)

autonomic [aw-tuh-NAHM-ik] **nervous system (ANS)** the part of the peripheral nervous system that controls the glands and the muscles of the internal organs (such as the heart). Its sympathetic division arouses; its parasympathetic division calms. (p. 87)

availability heuristic estimating the likelihood of events based on their availability in memory; if instances come readily to mind (perhaps because of their vividness), we presume such events are common. (p. 364)

aversive conditioning a type of counterconditioning that associates an unpleasant state (such as nausea) with an unwanted behavior (such as drinking alcohol). (p. 718)

axon the neuron extension that passes messages through its branches to other neurons or to muscles or glands. (p. 78)

babbling stage beginning at about 4 months, the stage of speech development in which the infant spontaneously utters various sounds at first unrelated to the household language. (p. 374)

barbiturates drugs that depress central nervous system activity, reducing anxiety but impairing memory and judgment. (p. 250)

basal metabolic rate the body's resting rate of energy expenditure. (p. 398)

basic research pure science that aims to increase the scientific knowledge base. (p. 14)

basic trust according to Erik Erikson, a sense that the world is predictable and trustworthy; said to be formed during infancy by appropriate experiences with responsive caregivers. (p. 492)

behavior genetics the study of the relative power and limits of genetic and environmental influences on behavior. (p. 124)

behavior therapy therapy that applies learning principles to the elimination of unwanted behaviors. (p. 716)

behavioral approach in personality theory, this perspective focuses on the effects of learning on our personality development. (p. 587)

behavioral psychology the scientific study of observable behavior, and its explanation by principles of learning. (p. 12)

behaviorism the view that psychology (1) should be an objective science that (2) studies behavior without reference to mental processes. Most research psychologists today agree with (1) but not with (2). (pp. 6, 266)

belief perseverance clinging to one's initial conceptions after the basis on which they were formed has been discredited. (p. 367)

binge-eating disorder significant binge-eating episodes, followed by distress, disgust, or guilt, but without the compensatory purging or fasting that marks bulimia nervosa. (p. 697)

binocular cues depth cues, such as retinal disparity, that depend on the use of two eyes. (p. 184)

biofeedback a system for electronically recording, amplifying, and feeding back information regarding a subtle physiological state, such as blood pressure or muscle tension. (p. 289)

biological psychology the scientific study of the links between biological (genetic, neural, hormonal) and psychological processes. (Some biological psychologists call themselves *behavioral neuroscientists*, *neuropsychologists*, *behavior geneticists*, *physiological psychologists*, or *biopsychologists*.) (pp. 12, 77)

biomedical therapy prescribed medications or procedures that act directly on the person's physiology. (p. 709)

biopsychosocial approach an integrated approach that incorporates biological, psychological, and social-cultural levels of analysis. (p. 11)

bipolar disorder a mood disorder in which a person alternates between the hopelessness and lethargy of depression and the overexcited state of mania. (Formerly called *manic-depressive disorder*.) (p. 673)

blind spot the point at which the optic nerve leaves the eye, creating a "blind" spot because no receptor cells are located there. (p. 173)

bottom-up processing analysis that begins with the sensory receptors and works up to the brain's integration of sensory information. (p. 152)

brainstem the oldest part and central core of the brain, beginning where the spinal cord swells as it enters the skull; the brainstem is responsible for automatic survival functions. (p. 97)

Broca's area controls language expression—an area of the frontal lobe, usually in the left hemisphere, that directs the muscle movements involved in speech. (p. 377)

bulimia nervosa an eating disorder in which a person alternates binge eating (usually of high-calorie foods) with purging (by vomiting or laxative use) or fasting. (p. 697)

bystander effect the tendency for any given bystander to be less likely to give aid if other bystanders are present. (p. 808)

Cannon-Bard theory the theory that an emotion-arousing stimulus simultaneously triggers (1) physiological responses and (2) the subjective experience of emotion. (p. 422)

case study a descriptive technique in which one individual or group is studied in depth in the hope of revealing universal principles. (p. 40)

catharsis in psychology, the idea that "releasing" aggressive energy (through action or fantasy) relieves aggressive urges. (p. 846)

central nervous system (CNS) the brain and spinal cord. (p. 86)

central route persuasion occurs when interested people focus on the arguments and respond with favorable thoughts. (p. 756)

cerebellum [sehr-uh-BELL-um] the "little brain" at the rear of the brainstem; functions include processing sensory input, coordinating movement output and balance, and enabling nonverbal learning and memory. (p. 98)

cerebral [seh-REE-bruhl] **cortex** the intricate fabric of interconnected neural cells covering the cerebral hemispheres; the body's ultimate control and information-processing center. (p. 104)

change blindness failing to notice changes in the environment. (p. 154)

chromosomes threadlike structures made of DNA molecules that contain the genes. (p. 124)

chunking organizing items into familiar, manageable units; often occurs automatically. (p. 323)

circadian [ser-KAY-dee-an] **rhythm** the biological clock; regular bodily rhythms (for example, of temperature and wakefulness) that occur on a 24-hour cycle. (p. 226)

classical conditioning a type of learning in which one learns to link two or more stimuli and anticipate events. (p. 266)

client-centered therapy a humanistic therapy, developed by Carl Rogers, in which the therapist uses techniques such as active listening within a genuine, accepting, empathic environment to facilitate clients' growth. (Also called *person-centered therapy*.) (p. 712)

clinical psychology a branch of psychology that studies, assesses, and treats people with psychological disorders. (p. 14)

cocaine a powerful and addictive stimulant, derived from the coca plant, producing temporarily increased alertness and euphoria. (p. 252)

cochlea [KOHK-lee-uh] a coiled, bony, fluid-filled tube in the inner ear; sound waves traveling through the cochlear fluid trigger nerve impulses. (p. 195)

cochlear implant a device for converting sounds into electrical signals and stimulating the auditory nerve through electrodes threaded into the cochlea. (p. 198)

cognition all the mental activities associated with thinking, knowing, remembering, and communicating. (pp. 356, 476)

cognitive dissonance theory the theory that we act to reduce the discomfort (dissonance) we feel when two of our thoughts (cognitions) are inconsistent. For example, when we become aware that our attitudes and our actions clash, we can reduce the resulting dissonance by changing our attitudes. (p. 759)

cognitive learning the acquisition of mental information, whether by observing events, by watching others, or through language. (p. 265)

cognitive map a mental representation of the layout of one's environment. For example, after exploring a maze, rats act as if they have learned a cognitive map of it. (p. 297)

cognitive neuroscience the interdisciplinary study of the brain activity linked with cognition (including perception, thinking, memory, and language). (pp. 7, 119)

cognitive psychology the scientific study of all the mental activities associated with thinking, knowing, remembering, and communicating. (p. 12)

cognitive therapy therapy that teaches people new, more adaptive ways of thinking; based on the assumption that thoughts intervene between events and our emotional reactions. (p. 720)

cognitive-behavioral therapy (CBT) a popular integrative therapy that combines cognitive therapy (changing self-defeating thinking) with behavior therapy (changing behavior). (p. 723)

cohort a group of people from a given time period. (p. 625)

collective unconscious Carl Jung's concept of a shared, inherited reservoir of memory traces from our species' history. (p. 566)

collectivism giving priority to the goals of one's group (often one's extended family or work group) and defining one's identity accordingly. (p. 599)

color constancy perceiving familiar objects as having consistent color, even if changing illumination alters the wavelengths reflected by the object. (p. 187)

community psychology a branch of psychology that studies how people interact with their social environments and how social institutions affect individuals and groups. (p. 15)

companionate love the deep affectionate attachment we feel for those with whom our lives are intertwined. (p. 803)

complementary and alternative medicine (CAM) as yet unproven health care treatments intended to supplement (complement) or serve as alternatives to conventional medicine, and which typically are not widely taught in medical schools, used in hospitals, or reimbursed by insurance companies. When research shows a therapy to be safe and effective, it usually then becomes part of accepted medical practice. (p. 863)

concept a mental grouping of similar objects, events, ideas, or people. (p. 356)

concrete operational stage in Piaget's theory, the stage of cognitive development (from about 6 or 7 to 11 years of age) during which children gain the mental operations that enable them to think logically about concrete events. (p. 483)

conditioned reinforcer a stimulus that gains its reinforcing power through its association with a primary reinforcer; also known as a *secondary reinforcer*. (p. 278)

conditioned response (CR) in classical conditioning, a learned response to a previously neutral (but now conditioned) stimulus (CS). (p. 268)

conditioned stimulus (CS) in classical conditioning, an originally irrelevant stimulus that, after association with an unconditioned stimulus (US), comes to trigger a conditioned response (CR). (p. 268)

conduction hearing loss hearing loss caused by damage to the mechanical system that conducts sound waves to the cochlea. (p. 197)

cones retinal receptor cells that are concentrated near the center of the retina and that function in daylight or in well-lit conditions. The cones detect fine detail and give rise to color sensations. (p. 173)

confirmation bias a tendency to search for information that supports our preconceptions and to ignore or distort contradictory evidence. (p. 362)

conflict a perceived incompatibility of actions, goals, or ideas. (p. 810)

conformity adjusting our behavior or thinking to coincide with a group standard. (p. 763)

confounding variable a factor other than the independent variable that might produce an effect in an experiment. (p. 52)

consciousness our awareness of ourselves and our environment. (pp. 118, 219)

conservation the principle (which Piaget believed to be a part of concrete operational reasoning) that properties such as mass, volume, and number remain the same despite changes in the forms of objects. (p. 479)

content validity the extent to which a test samples the behavior that is of interest. (p. 622)

continuous reinforcement reinforcing the desired response every time it occurs. (p. 279)

control group in an experiment, the group *not* exposed to the treatment; contrasts with the experimental group and serves as a comparison for evaluating the effect of the treatment. (p. 51)

convergent thinking narrows the available problem solutions to determine the single best solution. (p. 357)

conversion disorder a disorder in which a person experiences very specific genuine physical symptoms for which no physiological basis can be found. (Also called *functional neurological symptom disorder*.) (p. 694)

coping alleviating stress using emotional, cognitive, or behavioral methods. (p. 298)

coronary heart disease the clogging of the vessels that nourish the heart muscle; the leading cause of death in many developed countries. (p. 451)

corpus callosum [KOR-pus kah-LOW-sum] the large band of neural fibers connecting the two brain hemispheres and carrying messages between them. (p. 114)

correlation a measure of the extent to which two variables change together, and thus of how well either variable predicts the other. (p. 46)

correlation coefficient a statistical index of the relationship between two variables (from -1 to $+1$). (p. 46)

counseling psychology a branch of psychology that assists people with problems in living (often related to school, work, or marriage) and in achieving greater well-being. (p. 14)

counterconditioning behavior therapy procedures that use classical conditioning to evoke new responses to stimuli that are triggering unwanted behaviors; include *exposure therapies* and *aversive conditioning*. (p. 717)

creativity the ability to produce novel and valuable ideas. (p. 357)

critical period an optimal period early in the life of an organism when exposure to certain stimuli or experiences produces normal development. (p. 489)

critical thinking thinking that does not blindly accept arguments and conclusions. Rather, it examines assumptions, assesses the source, discerns hidden values, evaluates evidence, and assesses conclusions. (p. 35)

cross-sectional study a study in which people of different ages are compared with one another. (p. 543)

crystallized intelligence our accumulated knowledge and verbal skills; tends to increase with age. (p. 626)

CT (computed tomography) scan a series of X-ray photographs taken from different angles and combined by computer into a composite representation of a slice of the brain's structure. (Also called *CAT scan*.) (p. 95)

culture the enduring behaviors, ideas, attitudes, values, and traditions shared by a group of people and transmitted from one generation to the next. (pp. 65, 776)

debriefing the postexperimental explanation of a study, including its purpose and any deceptions, to its participants. (p. 68)

deep processing encoding semantically, based on the meaning of the words; tends to yield the best retention. (p. 325)

defense mechanisms in psychoanalytic theory, the ego's protective methods of reducing anxiety by unconsciously distorting reality. (p. 560)

deindividuation the loss of self-awareness and self-restraint occurring in group situations that foster arousal and anonymity. (p. 773)

déjà vu that eerie sense that "I've experienced this before." Cues from the current situation may unconsciously trigger retrieval of an earlier experience. (p. 349)

delta waves the large, slow brain waves associated with deep sleep. (p. 228)

delusions false beliefs, often of persecution or grandeur, that may accompany psychotic disorders. (p. 684)

dendrites a neuron's bushy, branching extensions that receive messages and conduct impulses toward the cell body. (p. 78)

dependent variable the outcome factor; the variable that may change in response to manipulations of the independent variable. (p. 52)

depressants drugs (such as alcohol, barbiturates, and opiates) that reduce neural activity and slow body functions. (p. 248)

depth perception the ability to see objects in three dimensions although the images that strike the retina are two-dimensional; allows us to judge distance. (p. 184)

descriptive statistics numerical data used to measure and describe characteristics of groups. Includes measures of central tendency and measures of variation. (p. 57)

developmental psychology a branch of psychology that studies physical, cognitive, and social change throughout the life span. (pp. 14, 462)

difference threshold the minimum difference between two stimuli required for detection 50 percent of the time. We experience the difference threshold as a *just noticeable difference* (or *jnd*). (p. 158)

discrimination (1) in classical conditioning, the learned ability to distinguish between a conditioned stimulus and stimuli that do not signal an unconditioned stimulus. (p. 270) (2) in social psychology, unjustifiable negative *behavior* toward a group and its members. (p. 780)

discriminative stimulus in operant conditioning, a stimulus that elicits a response after association with reinforcement (in contrast to related stimuli not associated with reinforcement). (p. 277)

dissociation a split in consciousness, which allows some thoughts and behaviors to occur simultaneously with others. (p. 222)

dissociative disorders disorders in which conscious awareness becomes separated (dissociated) from previous memories, thoughts, and feelings. (p. 694)

dissociative identity disorder (DID) a rare dissociative disorder in which a person exhibits two or more distinct and alternating personalities. Formerly called *multiple personality disorder*. (p. 695)

divergent thinking expands the number of possible problem solutions (creative thinking that diverges in different directions). (p. 357)

DNA (deoxyribonucleic acid) a complex molecule containing the genetic information that makes up the chromosomes. (p. 124)

double-blind procedure an experimental procedure in which both the research participants and the research staff are ignorant (blind) about whether the research participants have received the treatment or a placebo. Commonly used in drug-evaluation studies. (p. 51)

Down syndrome a condition of mild to severe intellectual disability and associated physical disorders caused by an extra copy of chromosome 21. (p. 629)

dream a sequence of images, emotions, and thoughts passing through a sleeping person's mind. Dreams are notable for their hallucinatory imagery, discontinuities, and incongruities, and for the dreamer's delusional acceptance of the content and later difficulties remembering it. (p. 240)

drive-reduction theory the idea that a physiological need creates an aroused tension state (a drive) that motivates an organism to satisfy the need. (p. 391)

DSM-5 the American Psychiatric Association's *Diagnostic and Statistical Manual of Mental Disorders*, Fifth Edition; a widely used system for classifying psychological disorders. (p. 654)

dual processing the principle that information is often simultaneously processed on separate conscious and unconscious tracks. (p. 120)

echoic memory a momentary sensory memory of auditory stimuli; if attention is elsewhere, sounds and words can still be recalled within 3 or 4 seconds. (p. 322)

eclectic approach an approach to psychotherapy that, depending on the client's problems, uses techniques from various forms of therapy. (p. 709)

Ecstasy (MDMA) a synthetic stimulant and mild hallucinogen. Produces euphoria and social intimacy, but with short-term health risks and longer-term harm to serotonin-producing neurons and to mood and cognition. (p. 253)

educational psychology the study of how psychological processes affect and can enhance teaching and learning. (p. 14)

effortful processing encoding that requires attention and conscious effort. (p. 320)

ego the largely conscious, "executive" part of personality that, according to Freud, mediates among the demands of the id, superego, and reality. The ego operates on the *reality principle*, satisfying the id's desires in ways that will realistically bring pleasure rather than pain. (p. 558)

egocentrism in Piaget's theory, the preoperational child's difficulty taking another's point of view. (p. 479)

electroconvulsive therapy (ECT) a biomedical therapy for severely depressed patients in which a brief electric current is sent through the brain of an anesthetized patient. (p. 743)

electroencephalogram (EEG) an amplified recording of the waves of electrical activity sweeping across the brain's surface. These waves are measured by electrodes placed on the scalp. (p. 95)

embodied cognition in psychological science, the influence of bodily sensations, gestures, and other states on cognitive preferences and judgments. (p. 211)

embryo the developing human organism from about 2 weeks after fertilization through the second month. (p. 466)

emerging adulthood for some people in modern cultures, a period from the late teens to mid-twenties, bridging the gap between adolescent dependence and full independence and responsible adulthood. (p. 523)

emotion a response of the whole organism, involving (1) physiological arousal, (2) expressive behaviors, and (3) conscious experience. (p. 421)

emotional intelligence the ability to perceive, understand, manage, and use emotions. (p. 612)

emotion-focused coping attempting to alleviate stress by avoiding or ignoring a stressor and attending to emotional needs related to one's stress reaction. (p. 298)

empirically derived test a test (such as the MMPI) developed by testing a pool of items and then selecting those that discriminate between groups. (p. 578)

empiricism the view that knowledge originates in experience and that science should, therefore, rely on observation and experimentation. (p. 3)

encoding the processing of information into the memory system—for example, by extracting meaning. (p. 319)

endocrine [EN-duh-krin] system the body's "slow" chemical communication system; a set of glands that secrete hormones into the bloodstream. (p. 90)

endorphins [en-DOR-fins] "morphine within"—natural, opiate-like neurotransmitters linked to pain control and to pleasure. (p. 82)

environment every external influence, from prenatal nutrition to the people and things around us. (p. 124)

epigenetics the study of environmental influences on gene expression that occur without a DNA change. (p. 131)

equity a condition in which people receive from a relationship in proportion to what they give to it. (p. 804)

estrogens sex hormones, such as estradiol, secreted in greater amounts by females than by males and contributing to female sex characteristics. In nonhuman female mammals, estrogen levels peak during ovulation, promoting sexual receptivity. (p. 408)

evidence-based practice clinical decision making that integrates the best available research with clinical expertise and patient characteristics and preferences. (p. 732)

evolutionary psychology the study of the evolution of behavior and mind, using principles of natural selection. (pp. 12, 135)

experiment a research method in which an investigator manipulates one or more factors (independent variables) to observe the effect on some behavior or mental process (the dependent variable). By *random assignment* of participants, the experimenter aims to control other relevant variables. (p. 51)

experimental group in an experiment, the group exposed to the treatment, that is, to one version of the independent variable. (p. 51)

experimental psychology the study of behavior and thinking using the experimental method. (p. 5)

explicit memory memory of facts and experiences that one can consciously know and "declare." (Also called *declarative memory*.) (p. 320)

exposure therapies behavioral techniques, such as *systematic desensitization* and *virtual reality exposure therapy*, that treat anxieties by exposing people (in imagination or actual situations) to the things they fear and avoid. (p. 717)

external locus of control the perception that chance or outside forces beyond our personal control determine our fate. (p. 300)

extinction the diminishing of a conditioned response; occurs in classical conditioning when an unconditioned stimulus (US) does not follow a conditioned stimulus (CS); occurs in operant conditioning when a response is no longer reinforced. (p. 269)

extrasensory perception (ESP) the controversial claim that perception can occur apart from sensory input; includes telepathy, clairvoyance, and precognition. (p. 167)

extrinsic motivation a desire to perform a behavior to receive promised rewards or avoid threatened punishment. (p. 298)

facial feedback effect the tendency of facial muscle states to trigger corresponding feelings such as fear, anger, or happiness. (p. 438)

factor analysis a statistical procedure that identifies clusters of related items (called *factors*) on a test; used to identify different dimensions of performance that underlie a person's total score. (p. 608)

false consensus effect the tendency to overestimate the extent to which others share our beliefs and our behaviors. (p. 568)

family therapy therapy that treats the family as a system. Views an individual's unwanted behaviors as influenced by, or directed at, other family members. (p. 724)

feature detectors nerve cells in the brain that respond to specific features of the stimulus, such as shape, angle, or movement. (p. 175)

feel-good, do-good phenomenon people's tendency to be helpful when already in a good mood. (p. 847)

fetal alcohol syndrome (FAS) physical and cognitive abnormalities in children caused by a pregnant woman's heavy drinking. In severe cases, signs include a small, out-of-proportion head and abnormal facial features. (p. 467)

fetus the developing human organism from 9 weeks after conception to birth. (p. 466)

figure-ground the organization of the visual field into objects (the *figures*) that stand out from their surroundings (the *ground*). (p. 183)

fixation according to Freud, a lingering focus of pleasure-seeking energies at an earlier psychosexual stage, in which conflicts were unresolved. (p. 560)

fixed-interval schedule in operant conditioning, a reinforcement schedule that reinforces a response only after a specified time has elapsed. (p. 280)

fixed-ratio schedule in operant conditioning, a reinforcement schedule that reinforces a response only after a specified number of responses. (p. 279)

flashbulb memory a clear memory of an emotionally significant moment or event. (p. 332)

flow a completely involved, focused state of consciousness, with diminished awareness of self and time, resulting from optimal engagement of one's skills. (p. 827)

fluid intelligence our ability to reason speedily and abstractly; tends to decrease during late adulthood. (p. 626)

fMRI (functional MRI) a technique for revealing bloodflow and, therefore, brain activity by comparing successive MRI scans. fMRI scans show brain function as well as its structure. (p. 96)

foot-in-the-door phenomenon the tendency for people who have first agreed to a small request to comply later with a larger request. (p. 757)

formal operational stage in Piaget's theory, the stage of cognitive development (normally beginning about age 12) during which people begin to think logically about abstract concepts. (p. 483)

fovea the central focal point in the retina, around which the eye's cones cluster. (p. 173)

framing the way an issue is posed; how an issue is framed can significantly affect decisions and judgments. (p. 368)

fraternal twins (dizygotic twins) twins who develop from separate fertilized eggs. They are genetically no closer than brothers and sisters, but they share a fetal environment. (p. 125)

free association in psychoanalysis, a method of exploring the unconscious in which the person relaxes and says whatever comes to mind, no matter how trivial or embarrassing. (p. 557)

frequency the number of complete wavelengths that pass a point in a given time (for example, per second). (p. 195)

frequency theory in hearing, the theory that the rate of nerve impulses traveling up the auditory nerve matches the frequency of a tone, thus enabling us to sense its pitch. (p. 199)

frontal lobes portion of the cerebral cortex lying just behind the forehead; involved in speaking and muscle movements and in making plans and judgments. (p. 105)

frustration-aggression principle the principle that frustration—the blocking of an attempt to achieve some goal—creates anger, which can generate aggression. (p. 791)

functionalism early school of thought promoted by James and influenced by Darwin; explored how mental and behavioral processes function—how they enable the organism to adapt, survive, and flourish. (p. 4)

fundamental attribution error the tendency for observers, when analyzing others' behavior, to underestimate the impact of the situation and to overestimate the impact of personal disposition. (p. 754)

gate-control theory the theory that the spinal cord contains a neurological "gate" that blocks pain signals or allows them to pass on to the brain. The "gate" is opened by the activity of pain signals traveling up small nerve fibers and is closed by activity in larger fibers or by information coming from the brain. (p. 203)

gender the socially constructed roles and characteristics by which a culture defines *male* and *female*. (p. 500)

gender identity our sense of being male or female. (p. 504)

gender role a set of expected behaviors for males or for females. (p. 503)

gender typing the acquisition of a traditional masculine or feminine role. (p. 504)

general adaptation syndrome (GAS) Selye's concept of the body's adaptive response to stress in three phases—alarm, resistance, exhaustion. (p. 444)

general intelligence (g) a general intelligence factor that, according to Spearman and others, underlies specific mental abilities and is therefore measured by every task on an intelligence test. (p. 608)

generalization the tendency, once a response has been conditioned, for stimuli similar to the conditioned stimulus to elicit similar responses. (p. 269)

generalized anxiety disorder an anxiety disorder in which a person is continually tense, apprehensive, and in a state of autonomic nervous system arousal. (p. 662)

genes the biochemical units of heredity that make up the chromosomes; segments of DNA capable of synthesizing proteins. (p. 124)

genome the complete instructions for making an organism, consisting of all the genetic material in that organism's chromosomes. (p. 124)

gestalt an organized whole. Gestalt psychologists emphasized our tendency to integrate pieces of information into meaningful wholes. (p. 182)

glial cells (glia) cells in the nervous system that support, nourish, and protect neurons; they may also play a role in learning and thinking. (p. 104)

glucose the form of sugar that circulates in the blood and provides the major source of energy for body tissues. When its level is low, we feel hunger. (p. 397)

grammar in a language, a system of rules that enables us to communicate with and understand others. In a given language, *semantics* is the set of rules for deriving meaning from sounds, and *syntax* is the set of rules for combining words into grammatically sensible sentences. (p. 373)

GRIT Graduated and Reciprocated Initiatives in Tension-Reduction—a strategy designed to decrease international tensions. (p. 815)

grit in psychology, grit is passion and perseverance in the pursuit of long-term goals. (pp. 610, 834)

group polarization the enhancement of a group's prevailing inclinations through discussion within the group. (p. 774)

group therapy therapy conducted with groups rather than individuals, permitting therapeutic benefits from group interaction. (p. 723)

grouping the perceptual tendency to organize stimuli into coherent groups. (p. 183)

groupthink the mode of thinking that occurs when the desire for harmony in a decision-making group overrides a realistic appraisal of alternatives. (p. 775)

habituation decreasing responsiveness with repeated stimulation. As infants gain familiarity with repeated exposure to a visual stimulus, their interest wanes and they look away sooner. (pp. 264, 468)

hallucinations false sensory experiences, such as seeing something in the absence of an external visual stimulus. (pp. 228, 685)

hallucinogens psychedelic ("mind-manifesting") drugs, such as LSD, that distort perceptions and evoke sensory images in the absence of sensory input. (pp. 439, 856)

health psychology a subfield of psychology that provides psychology's contribution to behavioral medicine. (pp. 439, 856)

heritability the proportion of variation among individuals that we can attribute to genes. The heritability of a trait may vary, depending on the range of populations and environments studied. (pp. 129, 632)

heuristic a simple thinking strategy that often allows us to make judgments and solve problems efficiently; usually speedier but also more error-prone than *algorithms*. (p. 361)

hierarchy of needs Maslow's pyramid of human needs, beginning at the base with physiological needs that must first be satisfied before higher-level safety needs and then psychological needs become active. (p. 393)

higher-order conditioning a procedure in which the conditioned stimulus in one conditioning experience is paired with a new neutral stimulus, creating a second (often weaker) conditioned stimulus. For example, an animal that has learned that a tone predicts food might then learn that a light predicts the tone and begin responding to the light alone. (Also called *second-order conditioning*.) (p. 268)

hindsight bias the tendency to believe, after learning an outcome, that one would have foreseen it. (Also known as the *I-knew-it-all-along phenomenon*.) (p. 31)

histogram a bar graph depicting a frequency distribution. (p. 57)

hippocampus a neural center located in the limbic system; helps process explicit memories for storage. (p. 330)

homeostasis a tendency to maintain a balanced or constant internal state; the regulation of any aspect of body chemistry, such as blood glucose, around a particular level. (p. 391)

hormones chemical messengers that are manufactured by the endocrine glands, travel through the bloodstream, and affect other tissues. (p. 90)

hue the dimension of color that is determined by the wavelength of light; what we know as the color names *blue*, *green*, and so forth. (p. 172)

human factors psychology an I/O psychology subfield that explores how people and machines interact and how machines and physical environments can be made safe and easy to use. (pp. 14, 828)

humanistic psychology a historically significant perspective that emphasized the growth potential of healthy people. (p. 6)

humanistic theories view personality with a focus on the potential for healthy personal growth. (p. 571)

hypnosis a social interaction in which one person (the subject) responds to another person's (the hypnotist's) suggestion that certain perceptions, feelings, thoughts, or behaviors will spontaneously occur. (p. 219)

hypothalamus [hi-po-THAL-uh-muss] a neural structure lying below (*hypo*) the thalamus; it directs several maintenance activities (eating, drinking, body temperature), helps govern the endocrine system via the pituitary gland, and is linked to emotion and reward. (p. 99)

hypothesis a testable prediction, often implied by a theory. (p. 38)

iconic memory a momentary sensory memory of visual stimuli; a photographic or picture-image memory lasting no more than a few tenths of a second. (p. 322)

id a reservoir of unconscious psychic energy that, according to Freud, strives to satisfy basic sexual and aggressive drives. The id operates on the *pleasure principle*, demanding immediate gratification. (p. 558)

identical twins (*monozygotic twins*) twins who develop from a single fertilized egg that splits in two, creating two genetically identical organisms. (p. 125)

identification the process by which, according to Freud, children incorporate their parents' values into their developing superegos. (p. 559)

identity our sense of self; according to Erikson, the adolescent's task is to solidify a sense of self by testing and integrating various roles. (p. 519)

illness anxiety disorder a disorder in which a person interprets normal physical sensations as symptoms of a disease. (Formerly called *hypochondriasis*.) (p. 694)

illusory correlation the perception of a relationship where none exists. (p. 50)

implicit memory retention independent of conscious recollection. (Also called *nondeclarative memory*.) (p. 320)

imprinting the process by which certain animals form strong attachments during an early life critical period. (p. 489)

inattention blindness failing to see visible objects when our attention is directed elsewhere. (p. 154)

incentive a positive or negative environmental stimulus that motivates behavior. (p. 392)

independent variable the experimental factor that is manipulated; the variable whose effect is being studied. (p. 52)

individualism giving priority to one's own goals over group goals and defining one's identity in terms of personal attributes rather than group identifications. (p. 598)

industrial-organizational (I/O) psychology the application of psychological concepts and methods to optimizing human behavior in workplaces. (pp. 14, 828)

inferential statistics numerical data that allow one to generalize—to infer from sample data the probability of something being true of a population. (p. 60)

informational social influence influence resulting from one's willingness to accept others' opinions about reality. (p. 764)

informed consent an ethical principle that research participants be told enough to enable them to choose whether they wish to participate. (p. 68)

ingroup "Us"—people with whom we share a common identity. (p. 784)

ingroup bias the tendency to favor our own group. (p. 784)

inner ear the innermost part of the ear, containing the cochlea, semicircular canals, and vestibular sacs. (p. 195)

insight a sudden realization of a problem's solution; contrasts with strategy-based solutions. (pp. 297, 361)

insight therapies a variety of therapies that aim to improve psychological functioning by increasing a person's awareness of underlying motives and defenses. (p. 711)

insomnia recurring problems in falling or staying asleep. (p. 238)

instinct a complex behavior that is rigidly patterned throughout a species and is unlearned. (p. 391)

intellectual disability a condition of limited mental ability, indicated by an intelligence score of 70 or below and difficulty in adapting to the demands of life. (Formerly referred to as *mental retardation*.) (p. 629)

intelligence mental quality consisting of the ability to learn from experience, solve problems, and use knowledge to adapt to new situations. (p. 607)

intelligence quotient (IQ) defined originally as the ratio of mental age (*ma*) to chronological age (*ca*) multiplied by 100 (thus, $IQ = ma/ca \times 100$). On contemporary intelligence tests, the average performance for a given age is assigned a score of 100, with scores assigned to relative performance above or below average. (p. 618)

intelligence test a method for assessing an individual's mental aptitudes and comparing them with those of others, using numerical scores. (p. 607)

intensity the amount of energy in a light or sound wave, which we perceive as brightness or loudness, as determined by the wave's amplitude. (p. 172)

interaction the interplay that occurs when the effect of one factor (such as environment) depends on another factor (such as heredity). (p. 131)

internal locus of control the perception that you control your own fate. (p. 300)

interneurons neurons within the brain and spinal cord that communicate internally and intervene between the sensory inputs and motor outputs. (p. 87)

interpretation in psychoanalysis, the analyst's noting supposed dream meanings, resistances, and other significant behaviors and events in order to promote insight. (p. 710)

intimacy in Erikson's theory, the ability to form close, loving relationships; a primary developmental task in late adolescence and early adulthood. (p. 521)

intrinsic motivation a desire to perform a behavior effectively for its own sake. (p. 297)

intuition an effortless, immediate, automatic feeling or thought, as contrasted with explicit, conscious reasoning. (p. 363)

iris a ring of muscle tissue that forms the colored portion of the eye around the pupil and controls the size of the pupil opening. (p. 172)

James-Lange theory the theory that our experience of emotion is our awareness of our physiological responses to emotion-arousing stimuli. (p. 421)

just-world phenomenon the tendency for people to believe the world is just and that people therefore get what they deserve and deserve what they get. (p. 784)

kinesthesia [kin-ehs-THÉE-see-a] the system for sensing the position and movement of individual body parts. (p. 209)

language our spoken, written, or signed words and the ways we combine them to communicate meaning. (p. 372)

latent content according to Freud, the underlying meaning of a dream (as distinct from its manifest content). (p. 241)

latent learning learning that occurs but is not apparent until there is an incentive to demonstrate it. (p. 297)

law of effect Thorndike's principle that behaviors followed by favorable consequences become more likely, and that behaviors followed by unfavorable consequences become less likely. (p. 275)

learned helplessness the hopelessness and passive resignation an animal or human learns when unable to avoid repeated aversive events. (p. 299)

learning the process of acquiring new and relatively enduring information or behaviors. (p. 263)

lens the transparent structure behind the pupil that changes shape to help focus images on the retina. (p. 172)

lesion [LEE-zhuhn] tissue destruction. A brain lesion is a naturally or experimentally caused destruction of brain tissue. (p. 94)

levels of analysis the differing complementary views, from biological to psychological to social-cultural, for analyzing any given phenomenon. (p. 11)

limbic system neural system (including the *hippocampus*, *amygdala*, and *hypothalamus*) located below the cerebral hemispheres; associated with emotions and drives. (p. 98)

linguistic determinism Whorf's hypothesis that language determines the way we think. (p. 379)

lobotomy a psychosurgical procedure once used to calm uncontrollably emotional or violent patients. The procedure cut the nerves connecting the frontal lobes to the emotion-controlling centers of the inner brain. (p. 746)

longitudinal study research in which the same people are restudied and retested over a long period. (p. 543)

long-term memory the relatively permanent and limitless storehouse of the memory system. Includes knowledge, skills, and experiences. (p. 319)

long-term potentiation (LTP) an increase in a cell's firing potential after brief, rapid stimulation. Believed to be a neural basis for learning and memory. (p. 333)

LSD a powerful hallucinogenic drug; also known as acid (*lysergic acid diethylamide*). (p. 254)

lymphocytes the two types of white blood cells that are part of the body's immune system: *B lymphocytes* form in the bone marrow and release antibodies that fight bacterial infections; *T lymphocytes* form in the thymus and other lymphatic tissue and attack cancer cells, viruses, and foreign substances. (p. 448)

major depressive disorder a mood disorder in which a person experiences, in the absence of drugs or another medical condition, two or more weeks with five or more symptoms, at least one of which must be either (1) depressed mood or (2) loss of interest or pleasure. (p. 672)

mania a mood disorder marked by a hyperactive, wildly optimistic state. (p. 673)

manifest content according to Freud, the remembered story line of a dream (as distinct from its latent, or hidden, content). (p. 241)

maturation biological growth processes that enable orderly changes in behavior, relatively uninfluenced by experience. (p. 471)

mean the arithmetic average of a distribution, obtained by adding the scores and then dividing by the number of scores. (p. 57)

median the middle score in a distribution; half the scores are above it and half are below it. (p. 57)

medical model the concept that diseases, in this case psychological disorders, have physical causes that can be *diagnosed, treated,* and, in most cases, *cured,* often through treatment in a *hospital*. (p. 653)

medulla [muh-DUL-uh] the base of the brainstem; controls heart-beat and breathing. (p. 97)

memory the persistence of learning over time through the encoding, storage, and retrieval of information. (p. 318)

menarche [meh-NAR-key] the first menstrual period. (p. 527)

menopause the time of natural cessation of menstruation; also refers to the biological changes a woman experiences as her ability to reproduce declines. (p. 540)

mental age a measure of intelligence test performance devised by Binet; the chronological age that most typically corresponds to a given level of performance. Thus, a child who does as well as the average 8-year-old is said to have a mental age of 8. (p. 618)

mental set a tendency to approach a problem in one particular way, often a way that has been successful in the past. (p. 362)

mere exposure effect the phenomenon that repeated exposure to novel stimuli increases liking of them. (p. 798)

meta-analysis a procedure for statistically combining the results of many different research studies. (p. 731)

methamphetamine a powerfully addictive drug that stimulates the central nervous system, with speeded-up body functions and associated energy and mood changes; over time, appears to reduce baseline dopamine levels. (p. 253)

middle ear the chamber between the eardrum and cochlea containing three tiny bones (hammer, anvil, and stirrup) that concentrate the vibrations of the eardrum on the cochlea's oval window. (p. 195)

Minnesota Multiphasic Personality Inventory (MMPI) the most widely researched and clinically used of all personality tests. Originally developed to identify emotional disorders (still considered its most appropriate use), this test is now used for many other screening purposes. (p. 578)

mirror neurons frontal lobe neurons that some scientists believe fire when performing certain actions or when observing another doing so. The brain's mirroring of another's action may enable imitation and empathy. (p. 304)

mirror-image perceptions mutual views often held by conflicting people, as when each side sees itself as ethical and peaceful and views the other side as evil and aggressive. (p. 812)

misinformation effect incorporating misleading information into one's memory of an event. (p. 347)

mnemonics [nih-MON-iks] memory aids, especially those techniques that use vivid imagery and organizational devices. (p. 323)

mode the most frequently occurring score(s) in a distribution. (p. 57)

modeling the process of observing and imitating a specific behavior. (p. 304)

molecular genetics the subfield of biology that studies the molecular structure and function of genes. (p. 129)

monocular cues depth cues, such as interposition and linear perspective, available to either eye alone. (p. 185)

mood disorders psychological disorders characterized by emotional extremes. See *major depressive disorder, mania,* and *bipolar disorder*. (p. 671)

mood-congruent memory the tendency to recall experiences that are consistent with one's current good or bad mood. (p. 337)

morpheme in a language, the smallest unit that carries meaning; may be a word or a part of a word (such as a prefix). (p. 373)

motivation a need or desire that energizes and directs behavior. (p. 390)

motor (efferent) neurons neurons that carry outgoing information from the brain and spinal cord to the muscles and glands. (p. 86)

motor cortex an area at the rear of the frontal lobes that controls voluntary movements. (p. 105)

MRI (magnetic resonance imaging) a technique that uses magnetic fields and radio waves to produce computer-generated images of soft tissue. MRI scans show brain anatomy. (p. 95)

mutation a random error in gene replication that leads to a change. (p. 136)

myelin [MY-uh-lin] **sheath** a fatty tissue layer segmentally encasing the axons of some neurons; enables vastly greater transmission speed as neural impulses hop from one node to the next. (p. 78)

narcissism excessive self-love and self-absorption. (p. 597)

narcolepsy a sleep disorder characterized by uncontrollable sleep attacks. The sufferer may lapse directly into REM sleep, often at inopportune times. (p. 238)

natural selection the principle that, among the range of inherited trait variations, those contributing to reproduction and survival will most likely be passed on to succeeding generations. (pp. 10, 135)

naturalistic observation observing and recording behavior in naturally occurring situations without trying to manipulate and control the situation. (p. 40)

nature-nurture issue the longstanding controversy over the relative contributions that genes and experience make to the development of psychological traits and behaviors. Today's science sees traits and behaviors arising from the interaction of nature and nurture. (p. 9)

near-death experience an altered state of consciousness reported after a close brush with death (such as through cardiac arrest); often similar to drug-induced hallucinations. (p. 255)

negative reinforcement increasing behaviors by stopping or reducing negative stimuli. A negative reinforcer is any stimulus that, when *removed* after a response, strengthens the response. (*Note:* Negative reinforcement is not punishment.) (p. 278)

nerves bundled axons that form neural “cables” connecting the central nervous system with muscles, glands, and sense organs. (p. 86)

nervous system the body’s speedy, electrochemical communication network, consisting of all the nerve cells of the peripheral and central nervous systems. (p. 86)

neurogenesis the formation of new neurons. (p. 112)

neuron a nerve cell; the basic building block of the nervous system. (p. 78)

neurotransmitters chemical messengers that cross the synaptic gaps between neurons. When released by the sending neuron, neurotransmitters travel across the synapse and bind to receptor sites on the receiving neuron, thereby influencing whether that neuron will generate a neural impulse. (p. 80)

neutral stimulus (NS) in classical conditioning, a stimulus that elicits no response before conditioning. (p. 266)

nicotine a stimulating and highly addictive psychoactive drug in tobacco. (p. 250)

night terrors a sleep disorder characterized by high arousal and an appearance of being terrified; unlike nightmares, night terrors occur during NREM-3 sleep, within two or three hours of falling asleep, and are seldom remembered. (p. 239)

norm an understood rule for accepted and expected behavior. Norms prescribe “proper” behavior. (p. 777)

normal curve (*normal distribution*) a symmetrical, bell-shaped curve that describes the distribution of many types of data; most scores fall near the mean (about 68 percent fall within one standard deviation of it) and fewer and fewer near the extremes. (pp. 59, 621)

normative social influence influence resulting from a person’s desire to gain approval or avoid disapproval. (p. 764)

NREM sleep nonrapid eye movement sleep; encompasses all sleep stages except for REM sleep. (p. 228)

object permanence the awareness that things continue to exist even when not perceived. (p. 478)

observational learning learning by observing others. (Also called *social learning*.) (p. 304)

obsessive-compulsive disorder (OCD) a disorder characterized by unwanted repetitive thoughts (obsessions) and/or actions (compulsions). (p. 663)

occipital [ahk-SIP-uh-tuhl] **lobes** portion of the cerebral cortex lying at the back of the head; includes areas that receive information from the visual fields. (p. 105)

Oedipus [ED-uh-puss] **complex** according to Freud, a boy’s sexual desires toward his mother and feelings of jealousy and hatred for the rival father. (p. 559)

one-word stage the stage in speech development, from about age 1 to 2, during which a child speaks mostly in single words. (p. 375)

operant behavior behavior that operates on the environment, producing consequences. (p. 289)

operant chamber in operant conditioning research, a chamber (also known as a *Skinner box*) containing a bar or key that an animal can manipulate to obtain a food or water reinforcer; attached devices record the animal’s rate of bar pressing or key pecking. (p. 276)

operant conditioning a type of learning in which behavior is strengthened if followed by a reinforcer or diminished if followed by a punisher. (p. 275)

operational definition a carefully worded statement of the exact procedures (operations) used in a research study. For example, *human intelligence* may be operationally defined as what an intelligence test measures. (p. 39)

opiates opium and its derivatives, such as morphine and heroin; they depress neural activity, temporarily lessening pain and anxiety. (p. 250)

opponent-process theory the theory that opposing retinal processes (red-green, yellow-blue, white-black) enable color vision. For example, some cells are stimulated by green and inhibited by red; others are stimulated by red and inhibited by green. (p. 179)

optic nerve the nerve that carries neural impulses from the eye to the brain. (p. 173)

organizational psychology an I/O psychology subfield that examines organizational influences on worker satisfaction and productivity and facilitates organizational change. (p. 828)

other-race effect the tendency to recall faces of one’s own race more accurately than faces of other races. (Also called the *cross-race effect* and the *own-race bias*.) (p. 786)

outgroup “Them”—those perceived as different or apart from our ingroup. (p. 784)

overconfidence the tendency to be more confident than correct—to overestimate the accuracy of our beliefs and judgments. (p. 365)

panic disorder an anxiety disorder marked by unpredictable, minutes-long episodes of intense dread in which a person experiences terror and accompanying chest pain, choking, or other frightening sensations. Often followed by worry over a possible next attack. (p. 662)

parallel processing the processing of many aspects of a problem simultaneously; the brain’s natural mode of information processing for many functions, including vision. Contrasts with the step-by-step (serial) processing of most computers and of conscious problem solving. (pp. 176, 319)

parapsychology the study of paranormal phenomena, including ESP and psychokinesis. (p. 167)

parasympathetic nervous system the division of the autonomic nervous system that calms the body, conserving its energy. (p. 87)

parietal [puh-RYE-uh-tuhl] **lobes** portion of the cerebral cortex lying at the top of the head and toward the rear; receives sensory input for touch and body position. (p. 105)

partial (intermittent) reinforcement reinforcing a response only part of the time; results in slower acquisition of a response but much greater resistance to extinction than does continuous reinforcement. (p. 279)

passionate love an aroused state of intense positive absorption in another, usually present at the beginning of a love relationship. (p. 803)

perception the process of organizing and interpreting sensory information, enabling us to recognize meaningful objects and events. (p. 152)

perceptual adaptation in vision, the ability to adjust to an artificially displaced or even inverted visual field. (p. 191)

perceptual constancy perceiving objects as unchanging (having consistent shapes, size, brightness, and color) even as illumination and retinal images change. (p. 186)

perceptual set a mental predisposition to perceive one thing and not another. (p. 163)

peripheral nervous system (PNS) the sensory and motor neurons that connect the central nervous system (CNS) to the rest of the body. (p. 86)

peripheral route persuasion occurs when people are influenced by incidental cues, such as a speaker's attractiveness. (p. 756)

personality an individual's characteristic pattern of thinking, feeling, and acting. (p. 555)

personality disorders psychological disorders characterized by inflexible and enduring behavior patterns that impair social functioning. (p. 698)

personality inventory a questionnaire (often with *true-false* or *agree-disagree* items) on which people respond to items designed to gauge a wide range of feelings and behaviors; used to assess selected personality traits. (p. 578)

personality psychology the study of an individual's characteristic pattern of thinking, feeling, and acting. (p. 14)

personnel psychology an I/O psychology subfield that focuses on employee recruitment, selection, placement, training, appraisal, and development. (p. 828)

PET (positron emission tomography) scan a visual display of brain activity that detects where a radioactive form of glucose goes while the brain performs a given task. (p. 95)

phi phenomenon an illusion of movement created when two or more adjacent lights blink on and off in quick succession. (p. 185)

phobia an anxiety disorder marked by a persistent, irrational fear and avoidance of a specific object, activity, or situation. (p. 662)

phoneme in a language, the smallest distinctive sound unit. (p. 373)

pitch a tone's experienced highness or lowness; depends on frequency. (p. 195)

pituitary gland the endocrine system's most influential gland. Under the influence of the hypothalamus, the pituitary regulates growth and controls other endocrine glands. (p. 91)

place theory in hearing, the theory that links the pitch we hear with the place where the cochlea's membrane is stimulated. (p. 199)

placebo [pluh-SEE-bo; Latin for "I shall please"] **effect** experimental results caused by expectations alone; any effect on behavior caused by the administration of an inert substance or condition, which the recipient assumes is an active agent. (p. 52)

plasticity the brain's ability to change, especially during childhood, by reorganizing after damage or by building new pathways based on experience. (p. 111)

polygraph a machine, commonly used in attempts to detect lies, that measures several of the physiological responses (such as perspiration and cardiovascular and breathing changes) accompanying emotion. (p. 428)

population all those in a group being studied, from which samples may be drawn. (*Note:* Except for national studies, this does *not* refer to a country's whole population.) (p. 43)

positive psychology the scientific study of human functioning, with the goals of discovering and promoting strengths and virtues that help individuals and communities to thrive. (pp. 15, 590)

positive reinforcement increasing behaviors by presenting positive reinforcers. A positive reinforcer is any stimulus that, when *presented* after a response, strengthens the response. (p. 277)

posthypnotic suggestion a suggestion, made during a hypnosis session, to be carried out after the subject is no longer hypnotized; used by some clinicians to help control undesired symptoms and behaviors. (p. 220)

posttraumatic growth positive psychological changes as a result of struggling with extremely challenging circumstances and life crises. (p. 665)

posttraumatic stress disorder (PTSD) a disorder characterized by haunting memories, nightmares, social withdrawal, jumpy anxiety, numbness of feeling, and/or insomnia that lingers for four weeks or more after a traumatic experience. (p. 664)

predictive validity the success with which a test predicts the behavior it is designed to predict; it is assessed by computing the correlation between test scores and the criterion behavior. (Also called *criterion-related validity*.) (pp. 345, 622)

prejudice an unjustifiable and usually negative *attitude* toward a group and its members. Prejudice generally involves stereotyped beliefs, negative feelings, and a predisposition to discriminatory action. (p. 780)

preoperational stage in Piaget's theory, the stage (from about 2 to about 6 or 7 years of age) during which a child learns to use language but does not yet comprehend the mental operations of concrete logic. (p. 479)

primary reinforcer an innately reinforcing stimulus, such as one that satisfies a biological need. (p. 278)

primary sex characteristics the body structures (ovaries, testes, and external genitalia) that make sexual reproduction possible. (p. 527)

priming the activation, often unconsciously, of certain associations, thus predisposing one's perception, memory, or response. (pp. 157, 336)

proactive interference the disruptive effect of prior learning on the recall of new information. (p. 345)

problem-focused coping attempting to alleviate stress directly—by changing the stressor or the way we interact with that stressor. (p. 298)

projective test a personality test, such as the Rorschach, that provides ambiguous stimuli designed to trigger projection of one's inner dynamics. (p. 567)

prosocial behavior positive, constructive, helpful behavior. The opposite of antisocial behavior. (p. 307)

prototype a mental image or best example of a category. Matching new items to a prototype provides a quick and easy method for sorting items into categories (as when comparing feathered creatures to a prototypical bird, such as a robin). (p. 356)

psychiatry a branch of medicine dealing with psychological disorders; practiced by physicians who sometimes provide medical (for example, drug) treatments as well as psychological therapy. (p. 15)

psychoactive drug a chemical substance that alters perceptions and moods. (p. 246)

psychoanalysis (1) Sigmund Freud's theory of personality that attributes thoughts and actions to unconscious motives and conflicts; the techniques used in treating psychological disorders by seeking to expose and interpret unconscious tensions. (p. 557) (2) Freud's therapeutic technique. Freud believed the patient's free associations, resistances, dreams, and transferences—and the therapist's interpretations of them—released previously repressed feelings, allowing the patient to gain self-insight. (p. 709)

psychodynamic psychology a branch of psychology that studies how unconscious drives and conflicts influence behavior, and uses that information to treat people with psychological disorders. (p. 12)

psychodynamic theories modern-day approaches that view personality with a focus on the unconscious and the importance of childhood experiences. (p. 565)

psychodynamic therapy therapy deriving from the psychoanalytic tradition that views individuals as responding to unconscious forces and childhood experiences, and that seeks to enhance self-insight. (p. 710)

psychological disorder a syndrome marked by a clinically significant disturbance in an individual's cognition, emotion regulation, or behavior. (Adapted from American Psychiatric Association, 2013.) (p. 651)

psychology the science of behavior and mental processes. (p. 7)

psychometrics the scientific study of the measurement of human abilities, attitudes, and traits. (p. 13)

psychoneuroimmunology the study of how psychological, neural, and endocrine processes together affect the immune system and resulting health. (p. 448)

psychopharmacology the study of the effects of drugs on mind and behavior. (p. 740)

psychophysics the study of relationships between the physical characteristics of stimuli, such as their intensity, and our psychological experience of them. (p. 155)

psychophysiological illness literally, "mind-body" illness; any stress-related physical illness, such as hypertension and some headaches. (p. 448)

psychosexual stages the childhood stages of development (oral, anal, phallic, latency, genital) during which, according to Freud, the id's pleasure-seeking energies focus on distinct erogenous zones. (p. 559)

psychosis a psychological disorder in which a person loses contact with reality, experiencing irrational ideas and distorted perceptions. (p. 684)

psychosurgery surgery that removes or destroys brain tissue in an effort to change behavior. (p. 746)

psychotherapy treatment involving psychological techniques; consists of interactions between a trained therapist and someone seeking to overcome psychological difficulties or achieve personal growth. (p. 709)

puberty the period of sexual maturation, during which a person becomes capable of reproducing. (p. 527)

punishment an event that tends to *decrease* the behavior that it follows. (p. 281)

pupil the adjustable opening in the center of the eye through which light enters. (p. 172)

random assignment assigning participants to experimental and control groups by chance, thus minimizing preexisting differences between the different groups. (p. 51)

random sample a sample that fairly represents a population because each member has an equal chance of inclusion. (p. 43)

range the difference between the highest and lowest scores in a distribution. (p. 58)

rational-emotive behavior therapy (REBT) a confrontational cognitive therapy, developed by Albert Ellis, that vigorously challenges people's illogical, self-defeating attitudes and assumptions. (p. 721)

recall a measure of memory in which the person must retrieve information learned earlier, as on a fill-in-the-blank test. (p. 334)

reciprocal determinism the interacting influences of behavior, internal cognition, and environment. (p. 588)

reciprocity norm an expectation that people will help, not hurt, those who have helped them. (p. 809)

recognition a measure of memory in which the person need only identify items previously learned, as on a multiple-choice test. (p. 334)

reflex a simple, automatic response to a sensory stimulus, such as the knee-jerk response. (p. 89)

refractory period (1) a period of inactivity after a neuron has fired. (p. 79) (2) a resting period after orgasm, during which a man cannot achieve another. (p. 407)

regression toward the mean the tendency for extreme or unusual scores to fall back (regress) toward their average. (p. 730)

reinforcement in operant conditioning, any event that *strengthens* the behavior it follows. (p. 276)

reinforcement schedule a pattern that defines how often a desired response will be reinforced. (p. 279)

relative deprivation the perception that we are worse off relative to those with whom we compare ourselves. (p. 851)

relearning a measure of memory that assesses the amount of time saved when learning material again. (p. 334)

reliability the extent to which a test yields consistent results, as assessed by the consistency of scores on two halves of the test, on alternate forms of the test, or on retesting. (p. 622)

REM rebound the tendency for REM sleep to increase following REM sleep deprivation (created by repeated awakenings during REM sleep). (p. 243)

REM sleep rapid eye movement sleep; a recurring sleep stage during which vivid dreams commonly occur. Also known as *paradoxical sleep*, because the muscles are relaxed (except for minor twitches) but other body systems are active. (p. 226)

repetitive transcranial magnetic stimulation (rTMS) the application of repeated pulses of magnetic energy to the brain; used to stimulate or suppress brain activity. (p. 745)

replication repeating the essence of a research study, usually with different participants in different situations, to see whether the basic finding extends to other participants and circumstances. (p. 39)

representativeness heuristic judging the likelihood of things in terms of how well they seem to represent, or match, particular prototypes; may lead us to ignore other relevant information. (p. 364)

repression in psychoanalytic theory, the basic defense mechanism that banishes from consciousness anxiety-arousing thoughts, feelings, and memories. (pp. 346, 560)

resilience the personal strength that helps most people cope with stress and recover from adversity and even trauma. (p. 737)

resistance in psychoanalysis, the blocking from consciousness of anxiety-laden material. (p. 710)

respondent behavior behavior that occurs as an automatic response to some stimulus. (p. 289)

reticular formation a nerve network that travels through the brainstem and thalamus and plays an important role in controlling arousal. (p. 98)

retina the light-sensitive inner surface of the eye, containing the receptor rods and cones plus layers of neurons that begin the processing of visual information. (p. 172)

retinal disparity a binocular cue for perceiving depth: By comparing images from the retinas in the two eyes, the brain computes distance—the greater the disparity (difference) between the two images, the closer the object. (p. 184)

retrieval the process of getting information out of memory storage. (p. 319)

retroactive interference the disruptive effect of new learning on the recall of old information. (p. 345)

retrograde amnesia an inability to retrieve information from one's past. (p. 342)

reuptake a neurotransmitter's reabsorption by the sending neuron. (p. 80)

rods retinal receptors that detect black, white, and gray; necessary for peripheral and twilight vision, when cones don't respond. (p. 173)

role a set of expectations (norms) about a social position, defining how those in the position ought to behave. (pp. 503, 758)

Rorschach inkblot test the most widely used projective test, a set of 10 inkblots, designed by Hermann Rorschach; seeks to identify people's inner feelings by analyzing their interpretations of the blots. (p. 567)

rumination compulsive fretting; *overthinking* about our problems and their causes. (p. 679)

sampling bias a flawed sampling process that produces an unrepresentative sample. (p. 43)

savant syndrome a condition in which a person otherwise limited in mental ability has an exceptional specific skill, such as in computation or drawing. (p. 609)

scapegoat theory the theory that prejudice offers an outlet for anger by providing someone to blame. (p. 785)

scatterplot a graphed cluster of dots, each of which represents the values of two variables. The slope of the points suggests the direction of the relationship between the two variables. The amount of scatter suggests the strength of the correlation (little scatter indicates high correlation). (p. 46)

schema a concept or framework that organizes and interprets information. (p. 477)

schizophrenia a psychological disorder characterized by delusions, hallucinations, disorganized speech, and/or diminished or inappropriate emotional expression. (p. 684)

secondary sex characteristics nonreproductive sexual traits, such as female breasts and hips, male voice quality, and body hair. (p. 527)

selective attention the focusing of conscious awareness on a particular stimulus. (p. 152)

self in contemporary psychology, assumed to be the center of personality, the organizer of our thoughts, feelings, and actions. (p. 594)

self-actualization according to Maslow, one of the ultimate psychological needs that arises after basic physical and psychological needs are met and self-esteem is achieved; the motivation to fulfill one's potential. (p. 571)

self-concept all our thoughts and feelings about ourselves, in answer to the question, "Who am I?" (pp. 492, 572)

self-control the ability to control impulses and delay short-term gratification for greater long-term rewards. (p. 301)

self-disclosure revealing intimate aspects of oneself to others. (p. 804)

self-efficacy one's sense of competence and effectiveness. (p. 595)

self-esteem one's feelings of high or low self-worth. (p. 595)

self-fulfilling prophecy a belief that leads to its own fulfillment. (p. 812)

self-serving bias a readiness to perceive oneself favorably. (p. 596)

sensation the process by which our sensory receptors and nervous system receive and represent stimulus energies from our environment. (p. 152)

sensorimotor stage in Piaget's theory, the stage (from birth to about 2 years of age) during which infants know the world mostly in terms of their sensory impressions and motor activities. (p. 478)

sensorineural hearing loss hearing loss caused by damage to the cochlea's receptor cells or to the auditory nerves. (Also called *nerve deafness*.) (p. 197)

sensory (afferent) neurons neurons that carry incoming information from the sensory receptors to the brain and spinal cord. (p. 86)

sensory adaptation diminished sensitivity as a consequence of constant stimulation. (p. 159)

sensory interaction the principle that one sense may influence another, as when the smell of food influences its taste. (p. 210)

sensory memory the immediate, very brief recording of sensory information in the memory system. (p. 319)

serial position effect our tendency to recall best the last (*a recency effect*) and first items (*a primacy effect*) in a list. (p. 337)

set point the point at which an individual's "weight thermostat" is supposedly set. When the body falls below this weight, an increase in hunger and a lowered metabolic rate may act to restore the lost weight. (p. 398)

sexual dysfunction a problem that consistently impairs sexual arousal or functioning. (p. 407)

sexual orientation an enduring sexual attraction toward members of either one's own sex (homosexual orientation), the other sex (heterosexual orientation), or both sexes (bisexual orientation). (p. 531)

sexual response cycle the four stages of sexual responding described by Masters and Johnson—excitement, plateau, orgasm, and resolution. (p. 406)

shallow processing encoding on a basic level based on the structure or appearance of words. (p. 324)

shaping an operant conditioning procedure in which reinforcers guide behavior toward closer and closer approximations of the desired behavior. (p. 276)

short-term memory activated memory that holds a few items briefly, such as the seven digits of a phone number while dialing, before the information is stored or forgotten. (p. 319)

signal detection theory a theory predicting how and when we detect the presence of a faint stimulus (*signal*) amid background stimulation (*noise*). Assumes there is no single absolute threshold and that detection depends partly on a person's experience, expectations, motivation, and alertness. (p. 156)

skewed distribution a representation of scores that lack symmetry around their average value. (p. 58)

sleep periodic, natural loss of consciousness—as distinct from unconsciousness resulting from a coma, general anesthesia, or hibernation. (Adapted from Dement, 1999.) (p. 227)

sleep apnea a sleep disorder characterized by temporary cessations of breathing during sleep and repeated momentary awakenings. (p. 239)

social anxiety disorder intense fear of social situations, leading to avoidance of such. (Formerly called *social phobia*.) (p. 662)

social clock the culturally preferred timing of social events such as marriage, parenthood, and retirement. (p. 544)

social exchange theory the theory that our social behavior is an exchange process, the aim of which is to maximize benefits and minimize costs. (p. 809)

social facilitation improved performance on simple or well-learned tasks in the presence of others. (p. 771)

social identity the “we” aspect of our self-concept; the part of our answer to “Who am I?” that comes from our group memberships. (p. 519)

social leadership group-oriented leadership that builds teamwork, mediates conflict, and offers support. (p. 838)

social learning theory the theory that we learn social behavior by observing and imitating and by being rewarded or punished. (p. 504)

social loafing the tendency for people in a group to exert less effort when pooling their efforts toward attaining a common goal than when individually accountable. (p. 773)

social psychology the scientific study of how we think about, influence, and relate to one another. (pp. 14, 754)

social script culturally modeled guide for how to act in various situations. (p. 792)

social trap a situation in which the conflicting parties, by each rationally pursuing their self-interest rather than the good of the group, become caught in mutually destructive behavior. (p. 810)

social-cognitive perspective views behavior as influenced by the interaction between people's traits (including their thinking) and their social context. (p. 587)

social-cultural psychology the study of how situations and cultures affect our behavior and thinking. (p. 12)

social-responsibility norm an expectation that people will help those needing their help. (p. 810)

somatic nervous system the division of the peripheral nervous system that controls the body's skeletal muscles. (Also called the *skeletal nervous system*.) (p. 87)

somatic symptom disorder a psychological disorder in which the symptoms take a somatic (bodily) form without apparent physical cause. (See *conversion disorder* and *illness anxiety disorder*.) (p. 693)

somatosensory cortex area at the front of the parietal lobes that registers and processes body touch and movement sensations. (p. 107)

source amnesia attributing to the wrong source an event we have experienced, heard about, read about, or imagined. (Also called *source misattribution*.) Source amnesia, along with the misinformation effect, is at the heart of many false memories. (p. 349)

spacing effect the tendency for distributed study or practice to yield better long-term retention than is achieved through massed study or practice. (p. 324)

split brain a condition resulting from surgery that isolates the brain's two hemispheres by cutting the fibers (mainly those of the corpus callosum) connecting them. (p. 114)

spontaneous recovery the reappearance, after a pause, of an extinguished conditioned response. (p. 269)

spotlight effect overestimating others' noticing and evaluating our appearance, performance, and blunders (as if we presume a spotlight shines on us). (p. 594)

SQ3R a study method incorporating five steps: Survey, Question, Read, Retrieve, Review. (p. 16)

standard deviation a computed measure of how much scores vary around the mean score. (p. 58)

standardization defining uniform testing procedures and meaningful scores by comparison with the performance of a pretested group. (p. 621)

Stanford-Binet the widely used American revision (by Terman at Stanford University) of Binet's original intelligence test. (p. 618)

statistical significance a statistical statement of how likely it is that an obtained result occurred by chance. (p. 60)

stereotype a generalized (sometimes accurate but often overgeneralized) *belief* about a group of people. (p. 780)

stereotype threat a self-confirming concern that one will be evaluated based on a negative stereotype. (p. 642)

stimulants drugs (such as caffeine, nicotine, and the more powerful amphetamines, cocaine, Ecstasy, and methamphetamine) that excite neural activity and speed up body functions. (p. 250)

stimulus any event or situation that evokes a response. (p. 264)

storage the process of retaining encoded information over time. (p. 319)

stranger anxiety the fear of strangers that infants commonly display, beginning by about 8 months of age. (p. 488)

stress the process by which we perceive and respond to certain events, called *stressors*, that we appraise as threatening or challenging. (p. 442)

structuralism early school of thought promoted by Wundt and Titchener; used introspection to reveal the structure of the human mind. (p. 4)

structured interviews an interview process that asks the same job-relevant questions of all applicants, each of whom is rated on established scales. (p. 832)

subjective well-being self-perceived happiness or satisfaction with life. Used along with measures of objective well-being (for example, physical and economic indicators) to evaluate people's quality of life. (p. 847)

subliminal below one's absolute threshold for conscious awareness. (p. 157)

substance use disorder continued substance craving and use despite significant life disruption and/or physical risk. (p. 246)

superego the part of personality that, according to Freud, represents internalized ideals and provides standards for judgment (the conscience) and for future aspirations. (p. 558)

superordinate goals shared goals that override differences among people and require their cooperation. (p. 813)

suprachiasmatic nucleus (SCN) a pair of cell clusters in the hypothalamus that controls circadian rhythm. In response to light, the SCN causes the pineal gland to adjust melatonin production, thus modifying our feelings of sleepiness. (p. 229)

survey a technique for ascertaining the self-reported attitudes or behaviors of a particular group, usually by questioning a representative, random sample of the group. (p. 42)

sympathetic nervous system the division of the autonomic nervous system that arouses the body, mobilizing its energy in stressful situations. (p. 87)

synapse [SIN-aps] the junction between the axon tip of the sending neuron and the dendrite or cell body of the receiving neuron. The tiny gap at this junction is called the *synaptic gap* or *synaptic cleft*. (p. 80)

systematic desensitization a type of exposure therapy that associates a pleasant, relaxed state with gradually increasing anxiety-triggering stimuli. Commonly used to treat phobias. (p. 717)

task leadership goal-oriented leadership that sets standards, organizes work, and focuses attention on goals. (p. 838)

telegraphic speech early speech stage in which a child speaks like a telegram—"go car"—using mostly nouns and verbs. (p. 375)

temperament a person's characteristic emotional reactivity and intensity. (p. 490)

temporal lobes portion of the cerebral cortex lying roughly above the ears; includes the auditory areas, each receiving information primarily from the opposite ear. (p. 105)

tend and befriend under stress, people (especially women) often provide support to others (tend) and bond with and seek support from others (befriend). (p. 445)

teratogens (literally, "monster makers") agents, such as chemicals and viruses, that can reach the embryo or fetus during prenatal development and cause harm. (p. 467)

terror-management theory a theory of death-related anxiety; explores people's emotional and behavioral responses to reminders of their impending death. (p. 568)

testing effect enhanced memory after retrieving, rather than simply rereading, information. Also sometimes referred to as a *retrieval practice* effect or *test-enhanced learning*. (pp. 16, 324)

testosterone the most important of the male sex hormones. Both males and females have it, but the additional testosterone in males stimulates the growth of the male sex organs in the fetus and the development of the male sex characteristics during puberty. (pp. 408, 526)

thalamus [THAL-uh-muss] the brain's sensory control center, located on top of the brainstem; it directs messages to the sensory receiving areas in the cortex and transmits replies to the cerebellum and medulla. (p. 97)

THC the major active ingredient in marijuana; triggers a variety of effects, including mild hallucinations. (p. 255)

Thematic Apperception Test (TAT) a projective test in which people express their inner feelings and interests through the stories they make up about ambiguous scenes. (p. 567)

theory an explanation using an integrated set of principles that organizes observations and predicts behaviors or events. (p. 38)

theory of mind people's ideas about their own and others' mental states—about their feelings, perceptions, and thoughts, and the behaviors these might predict. (p. 480)

therapeutic alliance a bond of trust and mutual understanding between a therapist and client, who work together constructively to overcome the client's problem. (p. 735)

threshold the level of stimulation required to trigger a neural impulse. (p. 80)

token economy an operant conditioning procedure in which people earn a token of some sort for exhibiting a desired behavior and can later exchange the tokens for various privileges or treats. (p. 719)

tolerance the diminishing effect with regular use of the same dose of a drug, requiring the user to take larger and larger doses before experiencing the drug's effect. (p. 246)

top-down processing information processing guided by higher-level mental processes, as when we construct perceptions drawing on our experience and expectations. (p. 152)

trait a characteristic pattern of behavior or a disposition to feel and act, as assessed by self-report inventories and peer reports. (p. 576)

transduction conversion of one form of energy into another. In sensation, the transforming of stimulus energies, such as sights, sounds, and smells, into neural impulses our brain can interpret. (p. 155)

transference in psychoanalysis, the patient's transfer to the analyst of emotions linked with other relationships (such as love or hatred for a parent). (p. 710)

transgender an umbrella term describing people whose gender identity or expression differs from that associated with their birth sex. (p. 505)

two-factor theory the Schachter-Singer theory that to experience emotion one must (1) be physically aroused and (2) cognitively label the arousal. (p. 422)

two-word stage beginning about age 2, the stage in speech development during which a child speaks mostly in two-word statements. (p. 375)

Type A Friedman and Rosenman's term for competitive, hard-driving, impatient, verbally aggressive, and anger-prone people. (p. 452)

Type B Friedman and Rosenman's term for easygoing, relaxed people. (p. 452)

unconditional positive regard a caring, accepting, nonjudgmental attitude, which Carl Rogers believed would help clients to develop self-awareness and self-acceptance. (pp. 572, 712)

unconditioned response (UR) in classical conditioning, an unlearned, naturally occurring response (such as salivation) to an unconditioned stimulus (US) (such as food in the mouth). (p. 267)

unconditioned stimulus (US) in classical conditioning, a stimulus that unconditionally—naturally and automatically—triggers a response (UR). (p. 267)

unconscious according to Freud, a reservoir of mostly unacceptable thoughts, wishes, feelings, and memories. According to contemporary psychologists, information processing of which we are unaware. (p. 557)

validity the extent to which a test measures or predicts what it is supposed to. (See also *content validity* and *predictive validity*.) (pp. 53, 622)

variable-interval schedule in operant conditioning, a reinforcement schedule that reinforces a response at unpredictable time intervals. (p. 280)

variable-ratio schedule in operant conditioning, a reinforcement schedule that reinforces a response after an unpredictable number of responses. (p. 280)

vestibular sense the sense of body movement and position, including the sense of balance. (p. 209)

virtual reality exposure therapy an anxiety treatment that progressively exposes people to electronic simulations of their greatest fears, such as airplane flying, spiders, or public speaking. (p. 718)

visual cliff a laboratory device for testing depth perception in infants and young animals. (p. 184)

wavelength the distance from the peak of one light or sound wave to the peak of the next. Electromagnetic wavelengths vary from the short blips of cosmic rays to the long pulses of radio transmission. (p. 171)

Weber's law the principle that, to be perceived as different, two stimuli must differ by a constant minimum percentage (rather than a constant amount). (p. 158)

Wechsler Adult Intelligence Scale (WAIS) the WAIS is the most widely used intelligence test; contains verbal and performance (nonverbal) subtests. (p. 620)

Wernicke's area controls language reception—a brain area involved in language comprehension and expression; usually in the left temporal lobe. (p. 377)

withdrawal the discomfort and distress that follow discontinuing an addictive drug or behavior. (p. 247)

working memory a newer understanding of short-term memory that focuses on conscious, active processing of incoming auditory and visual-spatial information, and of information retrieved from long-term memory. (p. 320)

X chromosome the sex chromosome found in both men and women. Females have two X chromosomes; males have one. An X chromosome from each parent produces a female child. (p. 526)

Y chromosome the sex chromosome found only in males. When paired with an X chromosome from the mother, it produces a male child. (p. 526)

Yerkes-Dodson law the principle that performance increases with arousal only up to a point, beyond which performance decreases. (p. 392)

Young-Helmholtz trichromatic (three-color) theory the theory that the retina contains three different color receptors—one most sensitive to red, one to green, one to blue—which, when stimulated in combination, can produce the perception of any color. (p. 178)

zygote the fertilized egg; it enters a 2-week period of rapid cell division and develops into an embryo. (p. 466)

Glosario en Español

absolute threshold/umbral absoluto estímulo mínimo necesario para detectar un estímulo particular el 50 por ciento del tiempo. (p. 156)

accommodation/adaptación (1) ajuste de nuestros conceptos actuales (esquemas) con el propósito de incorporar nueva información. (p. 172) (2) proceso por el que el lente del ojo cambia de forma para enfocar objetos cercanos o lejanos en la retina. (p. 477)

achievement motivation/motivación de logro deseo de alcanzar un logro significativo; de dominar destrezas o ideas; de control; y de lograr un nivel muy alto. (p. 834)

achievement test/prueba de rendimiento prueba diseñada para evaluar lo que una persona ha aprendido. (p. 619)

acquisition/adquisición fase inicial del condicionamiento clásico en la que se asocia un estímulo neutro con un estímulo no condicionado de manera que el estímulo neutro comience a provocar la respuesta condicionada. En el condicionamiento operante, se refiere a la consolidación de una respuesta reforzada. (p. 268)

action potential/potencial de acción impulso neural; carga eléctrica breve que se transmite por un axón. (p. 78)

active listening/escucha activa escucha empática en la que el oyente hace eco, reitera y clarifica. Una característica de la terapia de Rogers centrada en el cliente. (p. 712)

adaptation-level phenomenon/fenómeno del nivel de adaptación nuestra tendencia de formar juicios (de sonidos, de luces, de ingreso) relacionado a un nivel neutro definido por nuestra experiencia de antes. (p. 851)

addiction/adicción deseo compulsivo de usar drogas o llevar a cabo determinadas conductas (como apostar), a pesar de consecuencias desfavorables ya conocidas. (p. 247)

adolescence/adolescencia período de transición de la niñez a la madurez, extendiéndose de la pubertad a la independencia. (p. 513)

adrenal glands/glándulas suprarrenales par de glándulas endocrinas localizadas en la parte superior de los riñones. Estas glándulas secretan hormonas (epinefrina y norepinefrina) que estimulan el cuerpo en momentos de estrés. (p. 91)

aerobic exercise/ejercicio aeróbico ejercicio continuo que fortalece el corazón y los pulmones; también puede aliviar la depresión y la ansiedad. (p. 859)

aggression/agresión comportamiento expresado de manera física o verbal con el propósito de herir o destruir. (pp. 501, 789)

agonist/agonista molécula que, al unirse a un receptor, estimula una respuesta. (p. 82)

agoraphobia/agorafobia temor o tendencia a evitar situaciones, como las multitudes o los espacios abiertos, en las que se ha sentido una pérdida de control o pánico. (p. 663)

AIDS (acquired immune deficiency syndrome)/SIDA (síndrome de inmunodeficiencia adquirida) infección de transmisión sexual, potencialmente mortal, causada por el *virus de la inmunodeficiencia humana* (VIH). El SIDA deteriora el sistema inmunológico, de manera que la persona se vuelve vulnerable a las infecciones. (p. 529)

alcohol use disorder/trastorno por consumo de alcohol (popularmente conocido como *alcoholismo*) Consumo de alcohol caracterizado por la tolerancia, la abstinencia y un impulso por continuar con su uso problemático. (p. 249)

algorithm/algoritmo regla o procedimiento metódico y lógico que garantiza la solución de un problema particular. Se contrapone al uso de la *heurística*, que es normalmente más rápido, pero también con más posibilidades de cometer errores. (p. 361)

all-or-none response/respuesta del todo o nada reacción en la que una neurona emite una descarga (con una respuesta completa) o no lo hace. (p. 80)

alpha waves/ritmo alfa ritmo con ondas cerebrales relativamente lentas que corresponden a un estado relajado y de vigilia. (p. 227)

altruism/altruismo consideración desinteresada por el bienestar de otros. (p. 807)

amphetamines/anfetaminas drogas que estimulan la actividad neural, causando aceleración de las funciones corporales y de los niveles de energía asociadas con estas así como cambios de humor. (p. 250)

amygdala/amígdala dos grupos neurales del tamaño de un frijol que forman parte del sistema límbico; están ligados a las emociones. (p. 99)

anorexia nervosa/anorexia nervosa o nerviosa trastorno alimenticio en el que una persona (generalmente una muchacha adolescente) se somete a una dieta de hambre a pesar de estar muy por debajo de su peso normal (15 por ciento o más). (p. 697)

antagonist/antagonista molécula que, al unirse a un receptor, inhibe o bloquea una respuesta. (pp. 83, 342)

anterograde amnesia/amnesia anterógrada incapacidad de generar nuevos recuerdos. (p. 342)

anti-anxiety drugs/medicamentos contra la ansiedad medicamentos que se emplean para controlar la ansiedad y la agitación. (p. 741)

antidepressant drugs/medicamentos antidepresivos medicamentos que se emplean para tratar la depresión y los trastornos de ansiedad, obsesivo compulsivo y de estrés postraumático. (Entre los medicamentos antidepresivos más utilizados están los *inhibidores selectivos de la recaptación de la serotonina*, SSRI por sus siglas en inglés). (p. 741)

antipsychotic drugs/medicamentos antipsicóticos medicamentos que se emplean para tratar la esquizofrenia y otros tipos de trastornos graves del pensamiento. (p. 741)

antisocial personality disorder/trastorno antisocial de la personalidad trastorno de la personalidad que se manifiesta cuando la persona (generalmente un hombre) no exhibe sentimiento de culpa por actuar con maldad, incluso hacia los amigos y miembros de la familia. Puede ser agresivo y cruel o un estafador listo. (p. 699)

anxiety disorders/trastornos de ansiedad trastornos psicológicos que se caracterizan por la preocupación y ansiedad crónicas o comportamientos desadaptados que reducen la ansiedad. (p. 661)

aphasia/afasia disfunción del lenguaje generalmente causado por una lesión al hemisferio izquierdo, ya sea en el área de Broca (problemas de articulación) o en el área de Wernicke (problemas de comprensión). (p. 377)

applied research/investigación aplicada estudio científico cuyo objetivo es resolver los problemas prácticos. (p. 14)

aptitude tests/prueba de aptitud prueba diseñada para predecir la actuación de una persona en el futuro; la *aptitud* es la capacidad de aprender. (p. 619)

assimilation/asimilación interpretación de nuevas experiencias según los esquemas previamente existentes. (p. 477)

association areas/áreas de asociación áreas de la corteza cerebral que no están involucradas en las funciones motoras o sensoriales primarias; más bien, están involucradas en las funciones mentales superiores como el aprender, recordar, pensar y hablar. (p. 109)

associative learning/aprendizaje asociativo el aprender que ciertos eventos ocurren juntos. Los eventos pueden ser dos estímulos (como en el condicionamiento clásico) o una respuesta y sus consecuencias (como en el condicionamiento operante). (p. 264)

attachment/apego vínculo emocional con otra persona; mostrado en niños pequeños quienes buscan cercanía física con la persona que los cuida y muestran angustia cuando se les separa de quien los cuida. (p. 488)

attention-deficit hyperactivity disorder (ADHD)/trastorno de déficit de atención con hiperactividad trastorno psicológico marcado por la aparición antes de los 7 años de uno o más de estos tres síntomas clave: falta de atención extrema, hiperactividad e impulsividad. (p. 652)

attitude/actitud sentimientos, a menudo basados en nuestras creencias, que nos predisponen para responder de una manera particular a objetos, personas y eventos. (p. 756)

attribution theory/teoría de atribución teoría que propone que explicamos la conducta de una persona atribuyéndosela a la situación o a la disposición de esa persona. (p. 754)

audition/audición sentido o acto de oír. (p. 194)

autism spectrum disorder (ASD)/trastorno del espectro autista (TEA) trastorno que se manifiesta en la niñez y que está marcado por deficiencias en la comunicación y la interacción social, y por intereses obsesivos y comportamientos repetitivos. (p. 481)

automatic processing/procesamiento automático codificación inconsciente de información incidental, tal como el espacio, el tiempo y la frecuencia, y de información bien sabida, como el significado de las palabras. (p. 320)

autonomic nervous system (ANS)/sistema nervioso autónomo (SNA) parte del sistema nervioso periférico que controla las glándulas y los músculos de los órganos internos (como el corazón). El sistema nervioso simpático alerta al cuerpo; el sistema nervioso parasimpático lo calma. (p. 87)

availability heuristic/heurística de disponibilidad acto de estimar la probabilidad de un evento, basándose en la facilidad con la que es recordado. Si los casos vienen prontamente a la mente (quizás debido a su intensidad), presumimos que tales eventos son comunes. (p. 364)

aversive conditioning/condicionamiento aversivo tipo de contracondicionamiento en el cual los efectos desagradables (como la náusea) son asociados con comportamientos no deseados (como beber alcohol). (p. 718)

axon/axón prolongación de una neurona a través de la cual transmite mensajes a otras neuronas, o bien a músculos o glándulas, mediante ramificaciones. (p. 78)

babbling stage/fase balbuciente fase del desarrollo del lenguaje que comienza aproximadamente a los 4 meses de edad, y en la cual el infante espontáneamente emite diversos sonidos que al principio no están relacionados con el idioma de la casa. (p. 374)

barbiturates/barbitúricos drogas que deprimen la actividad del sistema nervioso central, reduciendo la ansiedad, pero que afectan la memoria y el discernimiento. (p. 250)

basal metabolic rate/tasa de metabolismo basal cantidad de energía requerida por el organismo en reposo. (p. 398)

basic research/investigación básica ciencia pura que tiene como propósito aumentar la base del conocimiento científico. (p. 14)

basic trust/confianza básica según Erik Erikson, la percepción de que el mundo es predecible y fidedigno; esta percepción se forma durante la infancia a través de experiencias apropiadas con cuidadores sensibles. (p. 492)

behavior genetics/genética del comportamiento estudio del poder relativo y de los límites de las influencias genéticas y ambientales en el comportamiento. (p. 124)

behavior therapy/terapia del comportamiento terapia que aplica los principios de aprendizaje para lograr la eliminación de comportamientos no deseados. (p. 716)

behavioral approach/enfoque conductista en la teoría de la personalidad, perspectiva centrada en los efectos que tiene el aprendizaje en el desarrollo de nuestra personalidad. (p. 587)

behavioral psychology/psicología conductista el estudio científico del comportamiento observable, y su explicación por los principios de aprendizaje. (p. 12)

behaviorism/conductismo posición de que la psicología (1) debe ser una ciencia objetiva que (2) estudia el comportamiento sin referencia a los procesos mentales. La mayoría de los psicólogos en investigación hoy están de acuerdo con (1) pero no con (2). (pp. 6, 266)

belief perseverance/perseverancia de las creencias adhesión a las concepciones iniciales aun después de que la base para estas creencias ha sido desacreditada. (p. 367)

binge-eating disorder/trastorno de alimentación compulsiva episodios significativos de ingestión compulsiva de alimentos, seguidos de angustia, indignación o sentimientos de culpabilidad, que no están seguidos de las purgas o los ayunos con propósitos compensatorios que caracterizan a la bulimia nerviosa. (p. 697)

binocular cues/indicadores binoculares indicadores de profundidad, tales como la disparidad de la retina, que dependen del uso de los dos ojos. (p. 184)

biofeedback/bioretroalimentación sistema para registrar, amplificar y retroalimentar información por vía electrónica en relación con un estado psicológico sutil, como la presión arterial o la tensión muscular (p. 289)

biological psychology/psicología biológica estudio científico de las conexiones entre los procesos biológicos (genéticos, neurales, hormonales) y psicológicos. (Algunos biopsicólogos se denominan *neurocientíficos conductuales*, *neuropsicólogos*, *geneticistas de la conducta*, *psicólogos fisiológicos* o *biopsicólogos*). (pp. 12, 77)

biomedical therapy/terapia biomédica medicamentos recetados o procedimientos médicos que actúan directamente en la fisiología de la persona. (p. 709)

biopsychosocial approach/enfoque biopsicosocial enfoque integrado que incorpora niveles de análisis biológicos, psicológicos y socioculturales. (p. 11)

bipolar disorder/trastorno bipolar trastorno que afecta el estado de ánimo; la persona alterna entre la desesperanza y el letargo de la depresión y el estado eufórico de la manía. (Anteriormente se denominaba *trastorno maníaco-depresivo*). (p. 673)

blind spot/punto ciego punto en el que el nervio óptico abandona el ojo, creando un punto "ciego" porque allí no se encuentra ninguna célula receptora. (p. 173)

bottom-up processing/procesamiento de abajo para arriba análisis que empieza con los receptores sensoriales y continúa para arriba hasta que llega al centro de integración sensorial del cerebro. (p. 152)

brainstem/tronco encefálico parte más antigua y meollo del cerebro, empezando donde la médula espinal se inflama al entrar en el cráneo; el tronco encefálico es responsable por las funciones automáticas de supervivencia. (p. 97)

Broca's area/área de Broca controla la producción del lenguaje; área del lóbulo frontal, generalmente del hemisferio izquierdo, que dirige los movimientos musculares involucrados en el lenguaje. (p. 377)

bulimia nervosa/bulimia nerviosa trastorno de la alimentación por el que una persona alterna episodios de ingestión compulsiva (generalmente de alimentos de alto contenido calórico) con purgas (por vómitos o uso de laxantes) o períodos de ayuno. (p. 697)

bystander effect/efecto espectador tendencia que tienen las personas a no brindar ayuda si hay otras personas presentes. (p. 808)

Cannon-Bard theory/teoría de Cannon-Bard teoría según la cual un estímulo que despierta emociones simultáneamente puede provocar (1) respuestas fisiológicas y (2) la experiencia subjetiva de la emoción. (p. 422)

case study/caso técnica descriptiva en la cual se estudia a un individuo o grupo a profundidad con la esperanza de revelar principios universales. (p. 40)

catharsis/catarsis en psicología, la idea de que "librar" la energía agresiva (a través de acción o fantasía) alivia los impulsos agresivos. (p. 846)

central nervous system (CNS)/sistema nervioso central (SNC) el cerebro y la médula espinal. (p. 86)

central route persuasion/persuasión por ruta central se observa cuando las personas interesadas se concentran en los argumentos y responden con pensamientos favorables. (p. 756)

cerebellum/cerebelo "cerebro pequeño" situado en la parte posterior del tronco encefálico; sus funciones incluyen procesar los estímulos sensoriales, coordinar el movimiento y el equilibrio, y permitir el aprendizaje no verbal y el funcionamiento de la memoria. (p. 98)

cerebral cortex/corteza cerebral tejido intrincado de células neurales interconectadas que cubren los hemisferios cerebrales; el centro de control y procesamiento de información del cuerpo. (p. 104)

change blindness/ceguera al cambio incapacidad de percibir cambios en el entorno. (p. 154)

chromosomes/cromosomas estructuras semejantes a hilos conformados de moléculas de ADN que contienen los genes. (p. 124)

chunking/división en pedazos el organizar los datos en unidades familiares y manejables; a menudo se da de manera automática. (p. 323)

circadian rhythm/ritmo circadiano reloj biológico; ritmos regulares del cuerpo (por ejemplo, temperatura y estado de vigilia) que ocurren en ciclos de 24 horas. (p. 226)

classical conditioning/condicionamiento clásico tipo de aprendizaje en el cual un individuo aprende a asociar dos o más estímulos y a anticipar hechos. (p. 266)

client-centered therapy/terapia centrada en el cliente terapia humanística, desarrollada por Carl Rogers, en la cual el terapeuta utiliza técnicas como el escuchar activamente dentro de un ambiente real de aceptación y empatía a fin de facilitar el crecimiento de los clientes. (También se la conoce como *terapia centrada en la persona*). (p. 712)

clinical psychology/psicología clínica rama de la psicología que estudia, evalúa y trata a las personas con trastornos psicológicos. (p. 14)

cocaine/cocaína estimulante potente y adictivo que se deriva de la planta de coca. Genera una actitud temporal de alerta y euforia. (p. 252)

cochlea/cóclea estructura ósea en forma de tubo enrollado en espiral, llena de fluidos, que se encuentra en el oído interno. A través de la cóclea las ondas sonoras activan los impulsos nerviosos. (p. 195)

cochlear implant/implante coclear dispositivo que convierte sonidos en signos eléctricos y estimula el nervio auditorio a través de electrodos implantados en la cóclea. (p. 198)

cognition/cognición todas las actividades mentales asociadas con el pensar, saber, recordar y comunicar. (pp. 356, 476)

cognitive dissonance theory/teoría de la disonancia cognitiva teoría que dice que cuando tenemos dos opiniones (cogniciones) que se contradicen, hacemos algo para reducir ese malestar (disonancia). Por ejemplo, cuando percibimos que nuestras actitudes y nuestras acciones chocan, podemos reducir la disonancia resultante cambiando nuestras actitudes. (p. 759)

cognitive learning/aprendizaje cognitivo adquisición de información mental, ya sea mediante la observación de eventos o de personas, o bien mediante el lenguaje. (p. 265)

cognitive map/mapa cognitivo representación mental del propio entorno. Por ejemplo, después de explorar un laberinto, las ratas se comportan como si hubiesen aprendido un mapa cognitivo de este. (p. 297)

cognitive neuroscience/neurociencia cognitiva estudio interdisciplinario de la actividad cerebral relacionada con la cognición (incluye la percepción, el pensamiento, la memoria y el lenguaje). (pp. 7, 119)

cognitive psychology/psicología cognoscitiva estudio científico de todas las actividades mentales relacionadas con el pensamiento, el saber, la memoria y la comunicación. (p. 12)

cognitive therapy/terapia cognitiva terapia que enseña a los pacientes a pensar y actuar de modos más realistas y adaptativos. Está basada en el supuesto de que los pensamientos intervienen entre los eventos y nuestras reacciones emocionales. (p. 720)

cognitive-behavioral therapy (CBT)/terapia cognitiva-conductual (TCC) terapia popular que integra la terapia cognitiva (cambiar el pensamiento de autoderrota) y la terapia conductual (modificar la conducta). (p. 723)

cohort/cohorte grupo de personas en un período determinado. (p. 625)

collective unconscious/inconsciente colectivo concepto de Carl Jung de un depósito de memorias de la historia de nuestra especie compartido por la humanidad. (p. 566)

collectivism/colectivismo el dar prioridad a las metas del grupo al que se pertenece (generalmente la familia extendida o el grupo de trabajo), definiendo de esta manera la propia identidad. (p. 599)

color constancy/constancia de color el percibir que los objetos familiares parecen mantener la apariencia cromática incluso cuando las ondas reflejadas por el objeto se ven alteradas por un cambio de iluminación. (p. 187)

community psychology/psicología comunitaria rama de la psicología que estudia la interacción entre las personas y sus ambientes sociales, así como también la manera en la que las instituciones sociales afectan a los individuos y los grupos. (p. 15)

companionate love/amor compañero apego afectuoso profundo que sentimos por aquellos con quienes nuestras vidas se entrelazan. (p. 803)

complementary and alternative medicine (CAM)/medicina complementaria y alternativa tratamientos de salud que aún no se han puesto a prueba y tienen el propósito de complementar o de servir como alternativas a la medicina convencional; generalmente no se enseñan en las escuelas de medicina, no son utilizados en los hospitales, ni son reembolsados por las compañías de seguros. Cuando los estudios demuestran que una terapia es segura y eficaz, por lo general esta pasa a formar parte de la práctica médica aceptada. (p. 863)

concept/concepto agrupación mental de objetos, eventos, ideas, o personas con características similares. (p. 356)

concrete operational stage/etapa del pensamiento lógico-concreto en la teoría de Piaget, la fase del desarrollo cognitivo (desde aproximadamente los 6 o 7 años hasta los 11 años de edad) durante la cual los niños desarrollan las operaciones mentales que les permiten pensar lógicamente sobre eventos concretos. (p. 483)

conditioned reinforcer/refuerzo condicionado estímulo que debe asociarse con un refuerzo primario para adquirir sus propiedades de reforzamiento. También se lo conoce como *refuerzo secundario*. (p. 278)

conditioned response (CR)/respuesta condicionada (RC) en el condicionamiento clásico, una respuesta aprendida a un estímulo previamente neutral (pero ahora condicionado) (p. 268)

conditioned stimulus (CS)/estímulo condicionado (EC) en el condicionamiento clásico, un estímulo originalmente irrelevante que, después de ser asociado con un estímulo incondicionado (EI) produce una respuesta condicionada (RC). (p. 268)

conduction hearing loss/pérdida auditiva conductiva pérdida de audición causada por daño al sistema mecánico que conduce las ondas sonoras a la cóclea. (p. 197)

cones/conos células receptoras de la retina que se concentran cerca del centro de la retina y que funcionan a la luz del día o en condiciones con buena iluminación. Los conos ayudan a percibir el color y los pequeños detalles. (p. 173)

confirmation bias/predisposición a buscar confirmación tendencia a buscar información que confirme nuestras ideas preconcebidas y a ignorar o distorsionar la evidencia contradictoria. (p. 362)

conflict/conflicto incompatibilidad percibida de acciones, metas o ideas. (p. 810)

conformity/conformidad el adaptar nuestro comportamiento o pensamiento para que coincida con una norma del grupo. (p. 763)

confounding variable/variable de confusión factor distinto de la variable independiente, que podría provocar un efecto en un experimento. (p. 52)

consciousness/conciencia percepción de nosotros mismos y de nuestro ambiente. (pp. 118, 219)

conservation/conservación principio de que las propiedades como la masa, el volumen y el número no varían a pesar de los cambios en las formas de los objetos. (Piaget era de la opinión de que este formaba parte de la etapa operacional concreta). (p. 479)

content validity/validez de contenido grado en el cual una prueba promueve el comportamiento que es de interés. (p. 622)

continuous reinforcement/refuerzo continuo el reforzar la respuesta deseada cada vez que ocurre. (p. 279)

control group/grupo control en un experimento, el grupo que *no* está expuesto al tratamiento; contrasta con el grupo experimental y sirve como comparación para evaluar el efecto del tratamiento. (p. 51)

convergent thinking/pensamiento convergente pensamiento que consiste en ir descartando las posibles soluciones a un problema hasta encontrar la mejor. (p. 357)

conversion disorder/trastorno de conversión trastorno en el que una persona experimenta síntomas físicos genuinos y muy específicos que no se pueden relacionar con una base fisiológica. (También se lo conoce como *trastorno por síntomas neurológicos funcionales*). (p. 694)

coping/afrentamiento el aliviar el estrés utilizando métodos emocionales, cognitivos o conductuales. (p. 298)

coronary heart disease/cardiopatía coronaria obstrucción de los vasos que nutren el músculo cardíaco; la causa principal de muerte en muchos países desarrollados. (p. 451)

corpus callosum/cuerpo calloso banda grande de fibras neurales que conecta los dos hemisferios del cerebro y lleva mensajes entre ellos. (p. 114)

correlation/correlación medida del grado en que dos variables cambian simultáneamente y, por ende, si es que una de ellas es capaz de predecir la otra. (p. 46)

correlation coefficient/coeficiente de correlación índice estadístico de la relación entre dos variables (de -1 a +1). (p. 46)

counseling psychology/psicología de orientación rama de la psicología que ayuda a las personas con sus problemas de la vida diaria (a menudo relacionados con la escuela, el trabajo o el matrimonio) y a aumentar su bienestar. (p. 14)

counterconditioning/contracondicionamiento procedimiento de terapia conductual en el que se emplea el condicionamiento clásico para producir nuevas respuestas a estímulos que provocan conductas no deseadas; incluye las *terapias de exposición* y el *condicionamiento aversivo*. (p. 717)

creativity/creatividad habilidad de producir ideas originales y valiosas. (p. 357)

critical period/período crítico período óptimo poco después del nacimiento cuando la exposición de un organismo a ciertos estímulos o experiencias produce un desarrollo normal. (p. 489)

critical thinking/pensamiento crítico pensamiento que no acepta argumentos y conclusiones a ciegas. Más bien examina las suposiciones, evalúa la fuente, percibe los valores ocultos, analiza la evidencia y evalúa las conclusiones. (p. 35)

cross-sectional study/estudio transversal estudio en el que se comparan personas de diferentes edades. (p. 543)

crystallized intelligence/inteligencia cristalizada el conocimiento y las destrezas verbales que acumulamos; tiende a aumentar con la edad. (p. 626)

CT (computed tomography) scan/tomografía computarizada (TC) una serie de fotografías de rayos X tomadas desde ángulos diferentes y combinadas mediante un ordenador en una representación compuesta de una sección de la estructura del cerebro. (También llamada *CAT scan* en inglés). (p. 95)

culture/cultura comportamientos duraderos, ideas, actitudes y tradiciones compartidos por un grupo de personas y transmitidos de una generación a la siguiente. (pp. 65, 776)

debriefing/aclaración postexperimental explicación de un estudio, incluyendo su finalidad y los posibles engaños, a sus participantes. (p. 68)

deep processing/procesamiento profundo codificación sistemática basada en el significado de las palabras; suele incrementar la retención. (p. 325)

defense mechanisms/mecanismos de defensa en la teoría psicoanalítica, los métodos de protección del ego para reducir la ansiedad distorsionando la realidad inconscientemente. (p. 560)

deindividuation/desindividualización pérdida de identidad personal y del autocontrol en situaciones de grupo que fomentan la excitación y el anonimato. (p. 773)

déjà vu/déjà vu sensación de haber vivido antes una experiencia específica. Señales de la presente situación pueden de manera subconsciente activar la recuperación de una experiencia previa. (p. 349)

delta waves/sondas delta ondas cerebrales amplias y lentas asociadas con el sueño profundo. (p. 228)

delusions/delirios creencias falsas, a menudo de persecución o grandeza, que pueden acompañar los trastornos psicóticos. (p. 684)

dendrites/dendritas extensiones ramificadas de una neurona que reciben los mensajes y emiten impulsos hacia el cuerpo celular. (p. 78)

dependent variable/variable dependiente factor resultante; la variable que puede cambiar en respuesta a cambios en la variable independiente. (p. 52)

depressants/depresivos drogas (como el alcohol, barbitúricos y opiáceos) que reducen la actividad neuronal y lentifican las funciones corporales. (p. 248)

depth perception/percepción de profundidad habilidad de ver objetos en tres dimensiones aunque las imágenes percibidas por la retina son bidimensionales. Esto nos permite juzgar la distancia. (p. 184)

descriptive statistics/estadística descriptiva datos numéricos utilizados para medir y describir las características de los grupos. Incluye las medidas de la tendencia central y de la variación. (p. 57)

developmental psychology/psicología del desarrollo rama de la psicología que estudia el cambio físico, cognitivo y social a lo largo de la vida. (pp. 14, 462)

difference threshold/umbral diferencial diferencia mínima requerida para distinguir un estímulo de otro el 50 por ciento de las veces. Experimentamos el umbral diferencial como una *diferencia apenas perceptible* (o *dap*). (p. 158)

discrimination/discriminación (1) en el condicionamiento clásico, la habilidad adquirida de distinguir entre un estímulo condicionado y aquellos estímulos que no señalan un estímulo sin condición. (p. 270) (2) en la psicología social, el *comportamiento* negativo injustificable hacia un grupo y sus miembros. (p. 780)

discriminative stimulus/estímulo discriminativo en el condicionamiento operante, un estímulo que provoca una respuesta después de la asociación con el refuerzo (en contraste a los estímulos relacionados no relacionados con el refuerzo). (p. 277)

dissociation/disociación separación de la conciencia que permite que algunos pensamientos y comportamientos ocurran simultáneamente con otros. (p. 222)

dissociative disorders/trastornos disociativos trastornos en los que el conocimiento consciente se separa (se disocia) de los recuerdos, pensamientos y sentimientos anteriores. (p. 694)

dissociative identity disorder (DID)/trastorno de identidad disociativo (TID) trastorno disociativo poco común en el que una persona exhibe dos o más personalidades distintas que se alternan. Anteriormente se denominaba *trastorno de personalidad múltiple*. (p. 695)

divergent thinking/pensamiento divergente pensamiento que consiste en expandir el número de posibles soluciones a un problema (pensamiento creativo que diverge en diferentes direcciones). (p. 357)

DNA (deoxyribonucleic acid)/ADN (ácido desoxirribonucleico) molécula compleja que contiene la información genética de la que se constituyen los cromosomas. (p. 124)

double-blind procedure/procedimiento doble ciego procedimiento experimental en el cual los participantes y el personal de la investigación ignoran (están ciegos) si los participantes de la investigación han recibido el tratamiento o un placebo. Normalmente se utiliza en los estudios de evaluación de drogas. (p. 51)

Down syndrome/síndrome de Down retraso mental de leve a severo y trastornos físicos asociados provocados por una copia adicional del cromosoma 21. (p. 629)

dream/sueño sucesión de imágenes, emociones y pensamientos que pasan a través de la mente de una persona durmiente. Los sueños se caracterizan por su fantasía alucinante, falta de ilación e incongruencias, y por la aceptación delirante del contenido de estos de parte del soñador y las dificultades posteriores para recordarlo. (p. 240)

drive-reduction theory/teoría de la reducción del impulso idea que una necesidad fisiológica crea un estado de mayor tensión (un impulso) que motiva al organismo a satisfacer esta necesidad. (p. 391)

DSM-5/DSM-5 Manual diagnóstico y estadístico de trastornos mentales de la Asociación psiquiátrica estadounidense, quinta edición; sistema de amplia difusión para la clasificación de trastornos psicológicos. (p. 654)

dual processing/procesamiento dual principio que afirma que la información a menudo se procesa por vías conscientes e inconscientes separadas. (p. 120)

echoic memory/memoria ecoica memoria sensorial-auditiva de corto plazo; aunque la atención esté en otra parte, se pueden recordar sonidos y palabras en los siguientes 3 o 4 segundos. (p. 322)

eclectic approach/aproximación ecléctica enfoque de la psicoterapia que, dependiendo de los problemas del cliente, utiliza técnicas de distintas formas de terapia. (p. 709)

Ecstasy (MDMA)/éxtasis (MDMA) estimulante sintético y alucinógeno leve. Produce euforia e intimidad social, pero tiene riesgos de salud a corto plazo. Además, a largo plazo daña las neuronas que producen la serotonina, y afecta el ánimo y el proceso de cognición. (p. 253)

educational psychology/psicología educativa el estudio de cómo los procesos psicológicos afectan y pueden mejorar la enseñanza y el aprendizaje. (p. 14)

effortful processing/procesamiento con esfuerzo codificación que requiere atención y esfuerzo conscientes. (p. 320)

ego/ego parte en gran medida consciente y “ejecutiva” de la personalidad que, de acuerdo a Freud, media entre las demandas del id, el superego y la realidad. El ego opera bajo el *principio de realidad*, satisfaciendo los deseos del id en formas que de manera realista le brindarán placer y no dolor. (p. 558)

egocentrism/egocentrismo en la teoría de Piaget, la dificultad de los niños en la etapa preoperacional de aceptar el punto de vista ajeno. (p. 479)

electroconvulsive therapy (ECT)/terapia electroconvulsiva (TEC) terapia biomédica para pacientes severamente deprimidos en la que una corriente eléctrica de corta duración se envía a través del cerebro de un paciente anestesiado. (p. 743)

electroencephalogram (EEG)/electroencefalograma (EEG) registro en el que se amplifican las ondas de actividad eléctrica que recorren el cerebro. Estas ondas son medidas a través de electrodos colocados en el cuero cabelludo. (p. 95)

embodied cognition/cognición corpórea en psicología, la influencia que tienen las sensaciones corporales, los gestos y otros estados en las preferencias cognitivas y en la formación de juicios. (p. 211)

embryo/embrión etapa de desarrollo en el organismo humano a partir de las 2 semanas de fertilización hasta el segundo mes. (p. 466)

emerging adulthood/adulthood emergente entre algunos individuos de culturas modernas, etapa aproximadamente entre el final de la adolescencia y los veinticinco años de edad, en que se trata de salvar la brecha que se da entre la dependencia adolescente y la independencia completa del adulto responsable. (p. 523)

emotion/emoción reacción que involucra a todo el organismo, e incluye (1) excitación fisiológica, (2) comportamientos expresivos y (3) experiencia consciente. (p. 421)

emotional intelligence/inteligencia emocional habilidad de percibir, entender, administrar y utilizar las emociones. (p. 612)

emotion-focused coping/afrentamiento centrado en la emoción el intentar aliviar el estrés evitando o ignorando los estresores, y atendiendo a las necesidades emocionales relacionadas con la reacción al estrés. (p. 298)

empirically derived test/prueba empíricamente derivada prueba (tal como el MMPI) desarrollada a partir de un grupo de ítems y escogiendo aquellos que discriminan entre grupos. (p. 578)

empiricism/empirismo la visión de que el conocimiento se origina en la experiencia y de que ciencia debe, por lo tanto, basarse en la observación y la experimentación. (p. 3)

encoding/codificación el procesar información al sistema de memoria, por ejemplo, extrayendo el significado. (p. 319)

endocrine system/sistema endocrino sistema “lento” de comunicación química del cuerpo; un conjunto de glándulas que secretan hormonas al torrente sanguíneo. (p. 90)

endorphins/endorfinas “morfina interna”; neurotransmisores naturales similares a los opiáceos que están asociados con el control del dolor y con el placer. (p. 82)

environment/entorno toda influencia que no es de carácter genético, desde la nutrición prenatal hasta las personas y cosas que nos rodean. (p. 124)

epigenetics/epigenética estudio de las influencias del ambiente en la expresión génica sin que lleguen a producirse cambios en el ADN. (p. 131)

equity/equidad condición en la cual las personas reciben de manera proporcional lo que aportan a una relación. (p. 804)

estrogens/estrógenos hormonas sexuales, por ejemplo, el estradiol, secretadas en mayor cantidad en la mujer que en el hombre, que contribuye a formar las características sexuales de la mujer. En las mamíferas no humanas, los niveles de estrógeno alcanzan el nivel máximo durante la ovulación, promoviendo la receptividad sexual. (p. 408)

evidence-based practice/práctica basada en la evidencia toma de decisiones que combina los mejores estudios disponibles con la experiencia clínica y las características y preferencias del paciente. (p. 732)

evolutionary psychology/psicología evolutiva el estudio de la evolución de la conducta y la mente que utiliza los principios de selección natural. (pp. 12, 135)

experiment/experimento método de investigación en el que un científico manipula uno o más factores (variables independientes) para observar el efecto en algún comportamiento o proceso mental (la variable dependiente). La *asignación aleatoria* de participantes tiene como finalidad controlar otras variables relevantes. (p. 51)

experimental group/grupo experimental durante un experimento, grupo que está expuesto al tratamiento, o sea, a una versión de la variable independiente. (p. 51)

experimental psychology/psicología experimental el estudio de la conducta y el pensamiento por medio del método experimental. (p. 5)

explicit memory/memoria explícita recolección consciente de hechos y experiencias que uno puede “declarar.” (También denominada *memoria declaratoria*). (p. 320)

exposure therapies/terapias de exposición técnicas conductistas, como la *insensibilización sistemática* y la *terapia de exposición a una realidad virtual*, que tratan los estados de ansiedad exponiendo a las personas (en situaciones imaginarias o reales) a las cosas que temen y evitan. (p. 717)

external locus of control/locus de control externo percepción de que nuestra suerte o las fuerzas externas que existen más allá de nuestro control determinan nuestro destino. (p. 300)

extinction/extinción debilitación de la respuesta condicionada (RC); en el condicionamiento clásico ocurre cuando el estímulo incondicionado (EI) no viene detrás del estímulo condicionado (EC). En el condicionamiento operante la extinción ocurre cuando ya no se refuerza una respuesta específica. (p. 269)

extrasensory perception (ESP)/percepción extrasensorial (PES) afirmación controvertida de que es posible percibir por medios

distintos de los sentidos; incluye la telepatía, la clarividencia y la precognición. (p. 167)

extrinsic motivation/motivación extrínseca deseo de desempeñar un comportamiento con el propósito de recibir recompensas prometidas o evitar amenazas de castigo. (p. 298)

facial feedback effect/efecto de la reacción facial la tendencia de que los estados de los músculos faciales provoquen sentimientos acordes como el temor, la ira o la felicidad. (p. 438)

factor analysis/análisis factorial procedimiento estadístico que identifica grupos de artículos relacionados (llamados *factores*) en una prueba. Se utiliza para identificar distintas dimensiones de desempeño que determinan el puntaje total que recibe una persona. (p. 608)

false consensus effect/efecto del falso consenso tendencia a sobrestimar el grado en el que otros comparten nuestras creencias y conductas. (p. 568)

family therapy/terapia de familia terapia en la que se considera que la familia es un sistema. Según esta terapia, los comportamientos no deseados de un individuo son influenciados por otros miembros de la familia o dirigidos a estos. (p. 724)

feature detectors/detectores de características neuronas en el cerebro que responden a características específicas de un estímulo tales como forma, ángulo o movimiento. (p. 175)

feel-good, do-good phenomenon/fenómeno de sentirse bien, hacer el bien tendencia a ser serviciales cuando estamos de buen humor. (p. 847)

fetal alcohol syndrome (FAS)/síndrome de alcoholismo fetal (SAF) anomalías físicas y cognitivas en los niños causadas por la ingestión excesiva de alcohol por parte de las madres durante el embarazo. En casos agudos, los síntomas incluyen cráneo desproporcionadamente pequeño y características faciales anormales. (p. 467)

fetus/feto organismo humano en vías de desarrollo a partir de las 9 semanas de concepción hasta el nacimiento. (p. 466)

figure-ground/figura-fondo organización del campo visual en objetos (*figuras*) que se distinguen de sus ambientes (*fondos*). (p. 183)

fixation/fijación según Freud, un permanente foco de energía en busca de placer en una etapa psicosexual temprana cuando los conflictos todavía no estaban resueltos. (p. 560)

fixed-interval schedule/programa de intervalo fijo en el condicionamiento operante, un programa de refuerzo que solo refuerza una respuesta después de un lapso de tiempo específico. (p. 280)

fixed-ratio schedule/programa de frecuencia fija en el condicionamiento operante, un programa de refuerzo que solo refuerza una respuesta después de un número específico de respuestas. (p. 279)

flashbulb memory/memoria de flash memoria clara de un momento o evento emocionalmente significativo. (p. 332)

flow/flujo el sentirse completamente involucrado y concentrado en una actividad, de manera que se pierde la conciencia del yo y del tiempo. En consecuencia, se emplean las habilidades en todo su potencial. (p. 827)

fluid intelligence/inteligencia fluida capacidad que tenemos de razonar rápidamente y de manera abstracta; tiende a disminuir en los adultos muy mayores. (p. 626)

fMRI (functional magnetic resonance imaging)/imágenes de resonancia magnética funcional (IRMf) técnica para observar la circulación sanguínea y, por lo tanto, la actividad cerebral comparando resultados sucesivos de exámenes de resonancia magnética. Los resultados del examen de resonancia magnética funcional muestran la función y la estructura del cerebro. (p. 96)

foot-in-the-door phenomenon/fenómeno de pie en la puerta tendencia de la gente que ha accedido a algo pequeño en primer lugar, a después satisfacer una demanda más grande. (p. 757)

formal operational stage/periodo operacional formal en la teoría de Piaget, el período en el desarrollo cognitivo (normalmente empieza alrededor de los 12 años) durante el que la persona empieza a pensar lógicamente sobre conceptos abstractos. (p. 483)

fovea/fóvea punto central de enfoque de la retina alrededor del cual se agrupan los conos del ojo. (p. 173)

framing/enmarcamiento manera como se presenta una situación; el cómo se enmarca una situación puede afectar de manera significativa las decisiones y juicios. (p. 368)

fraternal twins (dizygotic twins)/mellizos (gemelos dicigóticos) se desarrollan de dos óvulos fecundados distintos. Genéticamente no están más cercanos que los hermanos y hermanas; pero comparten un medio ambiente fetal. (p. 125)

free association/asociación libre en psicoanálisis, un método de explorar el inconsciente en el que la persona se relaja y dice lo primero que le viene a la mente, no importa cuán trivial o incómodo sea. (p. 557)

frequency/frecuencia número de ondas completas que pasan un punto en un tiempo dado (por ejemplo, por segundo). (p. 195)

frequency theory/teoría de frecuencia en la audición, la teoría que postula que la proporción de impulsos nerviosos que viaja por el nervio auditivo es igual a la frecuencia de un tono, permitiéndonos percibir el tono. (p. 199)

frontal lobes/lóbulos frontales parte de la corteza cerebral que se halla inmediatamente detrás de la frente; tiene que ver con el habla y los movimientos musculares, así como la planificación y la formación de opiniones. (p. 105)

frustration-aggression principle/principio de frustración-agresión principio de que la frustración —el bloqueo de un intento para lograr alguna meta— crea ira, la cual puede generar agresión. (p. 791)

functionalism/funcionalismo escuela de psicología promovida por James e influida por Darwin; exploraba el funcionamiento de nuestros procesos mentales y conductuales, y cómo estos permiten que el organismo se adapte, sobreviva y prospere. (p. 4)

fundamental attribution error/error fundamental de la atribución tendencia de los observadores, al analizar la conducta de otra persona, a subestimar el impacto de la situación y a sobrestimar el impacto de la disposición personal. (p. 754)

gate-control theory/teoría de control de la puerta del dolor teoría que postula que la médula espinal contiene una “puerta” neurológica que bloquea las señales de dolor o les permite proseguir al cerebro. La “puerta” se abre por la actividad de las señales de dolor que viajan a través de pequeñas fibras nerviosas y se cierra por la actividad en las fibras más grandes o por información procedente del cerebro. (p. 203)

gender/género roles y características establecidos por la sociedad por los cuales una cultura define *hombre* y *mujer*. (p. 500)

gender identity/identidad de género sensación que tenemos de ser hombre o mujer. (p. 504)

gender role/rol de género expectativas de cómo las mujeres y los hombres deben comportarse. (p. 503)

gender typing/tipificación de género adquisición de un rol masculino o femenino tradicional. (p. 504)

general adaptation syndrome (GAS)/síndrome de adaptación general (SAG) concepto de Selye que afirma que la respuesta de adaptación del cuerpo al estrés se presenta en tres etapas: alarma, resistencia y agotamiento. (p. 444)

general intelligence (g)/factor g de inteligencia general factor de inteligencia general que de acuerdo a Spearman y otros subyace habilidades mentales específicas y es por lo tanto cuantificado por cada tarea de las pruebas de inteligencia. (p. 608)

generalization/generalización tendencia, una vez que una respuesta ha sido condicionada, a que los estímulos similares al estímulo condicionado provoquen respuestas similares. (p. 269)

generalized anxiety disorder/trastorno de ansiedad generalizado trastorno de ansiedad en el que la persona está constantemente tensa, aprensiva, y en estado de excitación del sistema nervioso autónomo. (p. 662)

genes/genes unidades bioquímicas de la herencia que constituyen los cromosomas; segmentos de ADN capaces de sintetizar proteínas. (p. 124)

genome/genoma instrucciones completas para crear un organismo; consiste de todo el material genético en los cromosomas de ese organismo. (p. 124)

gestalt/Gestalt un todo organizado. Los psicólogos de la Gestalt pusieron énfasis en nuestra tendencia a integrar segmentos de información en todos significativos. (p. 182)

glial cells (glia)/células gliales células en el sistema nervioso que sostienen, nutren y protegen a las neuronas; posiblemente cumplan una función en el aprendizaje y el pensamiento. (p. 104)

glucose/glucosa forma de azúcar que circula en la sangre y provee de la mayor fuente de energía a los tejidos del cuerpo. Cuando su nivel es bajo, sentimos hambre. (p. 397)

grammar/gramática en un idioma, un sistema de reglas que nos permite comunicarnos y entendernos con otros. La *semántica* es el conjunto de reglas que permiten deducir el significado de los sonidos y la *sintaxis* es el conjunto de reglas que establecen cómo se deben combinar palabras para formar oraciones gramáticamente correctas. (p. 373)

GRIT/estrategia de de-escalamiento paso a paso GRIT (por sus siglas en inglés) estrategia diseñada para disminuir las tensiones internacionales. (p. 815)

grit/tenacidad en psicología, la tenacidad es la pasión y la perseverancia en la búsqueda de metas a largo plazo. (pp. 610, 834)

group polarization/efecto de polarización de grupo fortalecimiento de las posiciones imperantes en un grupo a través de discusiones del grupo. (p. 774)

group therapy/terapia grupal terapia realizada con grupos, en lugar de individuos, que aprovecha los beneficios terapéuticos de la interacción grupal. (p. 723)

grouping/agrupamiento tendencia perceptiva de organizar los estímulos en grupos coherentes. (p. 183)

groupthink/pensamiento del grupo modo de pensar que ocurre cuando el deseo de armonía en un grupo de toma de decisiones anula la evaluación objetiva de las alternativas. (p. 775)

habituation/habituación atenuación de la respuesta por una estimulación repetitiva. Conforme los infantes se familiarizan con un estímulo visual debido su exposición repetida a este, su interés desaparece y miran para otro lado más pronto. (pp. 264, 468)

hallucinations/alucinaciones experiencias sensoriales falsas, como ver algo sin recibir ningún estímulo visual externo. (pp. 228, 685)

hallucinogens/alucinógenos drogas psicodélicas (“que se manifiestan en la mente”), como el LSD, que distorsionan las percepciones y evocan imágenes sensoriales sin ninguna inducción sensorial. (pp. 439, 856)

health psychology/psicología de salud subdivisión de la psicología que contribuye a la medicina conductual. (pp. 439, 856)

heritability/heredabilidad proporción de variación entre individuos que podemos atribuir a los genes. La heredabilidad de una característica puede variar dependiendo del rango de las poblaciones y de los ambientes estudiados. (pp. 129, 632)

heuristic/heurística simple estrategia de pensamiento que nos permite formar juicios y resolver problemas de manera eficiente. Normalmente es más rápida que el utilizar *algoritmos*; pero también puede conducir a más errores. (p. 361)

hierarchy of needs/jerarquía de necesidades pirámide de necesidades humanas de Maslow, empezando en la base con las necesidades fisiológicas que se deben satisfacer antes de que se activen las necesidades de seguridad de nivel superior y luego las necesidades psicológicas. (p. 393)

higher-order conditioning/condicionamiento de orden superior procedimiento en el que el estímulo condicionado de una experiencia condicionada se presenta a la vez que un nuevo estímulo neutral, creando un segundo (por lo general más débil) estímulo condicionado. Por ejemplo, un animal que ha aprendido que un tono precede un alimento, podría aprender que una luz precede el tono y comenzar a responder solo a la luz. (También se denomina *condicionamiento de segundo orden*). (p. 268)

hindsight bias/distorsión retrospectiva tendencia a creer, después de saber un resultado, que uno lo habría previsto. (También se lo conoce como *el fenómeno de “yo ya lo sabía”*). (p. 31)

histogram/histograma gráfica de barras que muestra una distribución de frecuencia. (p. 57)

hippocampus/hipocampo centro neuronal que es parte del sistema límbico y contribuye al procesamiento de memorias explícitas para almacenarlas. (p. 330)

homeostasis/homeóstasis tendencia a mantener un estado interior equilibrado o constante; la regulación de cualquier aspecto químico del cuerpo, como la glucosa en sangre, a un nivel específico. (p. 391)

hormones/hormonas mensajeros químicos producidos por las glándulas endocrinas que circulan en el torrente sanguíneo y afectan a otros tejidos. (p. 90)

hue/tono dimensión del color determinada por la longitud de la onda luminosa; lo que conocemos como los nombres de los colores: *azul, verde*, etc. (p. 172)

human factors psychology/psicología de factores humanos división de la psicología industrial y organizacional que explora cómo las personas y máquinas actúan recíprocamente, y cómo las máqui-

nas y los ambientes físicos pueden hacerse seguros y fáciles de usar. (pp. 14, 828)

humanistic psychology/psicología humanista perspectiva históricamente significativa que enfatizaba el potencial de crecimiento de las personas sanas. (p. 6)

humanistic theories/teorías humanistas teorías que analizan la personalidad enfocándose en el potencial del individuo para lograr una evolución personal sana. (p. 571)

hypnosis/hipnosis interacción social en la que una persona (el sujeto) responde a la sugerencia de otra (el hipnotizador) de que ciertas percepciones, sentimientos, pensamientos o comportamientos ocurrirán espontáneamente. (p. 219)

hypothalamus/hipotálamo estructura neural localizada debajo (*hipo*) del tálamo; regula varias actividades de mantenimiento (comer, beber y la temperatura corporal), contribuye a dirigir el sistema endocrino a través de la glándula pituitaria, y está conectado con las emociones y las recompensas. (p. 99)

hypothesis/hipótesis predicción comprobable, a menudo implicada por una teoría. (p. 38)

iconic memory/memoria icónica tipo de memoria sensorial momentánea que reacciona a los estímulos visuales; memoria fotográfica o de imágenes que dura solo unas décimas de segundo. (p. 322)

id/id depósito de energía psíquica inconsciente que, según Freud, se esfuerza por satisfacer los impulsos sexuales y agresivos esenciales. El id opera bajo el *principio de placer*, exigiendo satisfacción inmediata. (p. 558)

identical twins (monozygotic twins)/gemelos (gemelos monocigóticos) se desarrollan a partir de un solo óvulo fecundado que se divide en dos, creando dos organismos con características genéticas idénticas. (p. 125)

identification/identificación proceso en el que, según Freud, los niños incorporan los valores de sus padres en sus súper-egos en vías de desarrollo. (p. 559)

identity/identidad idea que tenemos de nosotros mismos; según Erikson, el adolescente tiene la tarea de solidificar su sentido de identidad probando e integrando diversos roles. (p. 519)

illness anxiety disorder/trastorno de ansiedad por enfermedad trastorno por el que una persona interpreta las sensaciones físicas normales como síntomas de una enfermedad. (Anteriormente se denominaba *hipocondría*). (p. 694)

illusory correlation/correlación ilusoria percepción de una relación donde no hay ninguna. (p. 50)

implicit memory/memoria implícita retención que es independiente de la memoria consciente. (También se denomina *memoria no declarativa*). (p. 320)

imprinting/impronta proceso en el que ciertos animales forman apegos durante un período crítico muy temprano en la vida. (p. 489)

inattention blindness/ceguera por falta de atención el no ver los objetos visibles cuando nuestra atención se dirige a otra parte. (p. 154)

incentive/incentivo estímulo medioambiental positivo o negativo que motiva el comportamiento. (p. 392)

independent variable/variable independiente factor experimental que se manipula; la variable cuyo efecto es el objeto de estudio. (p. 52)

individualism/individualismo el dar prioridad a las propias metas sobre las metas del grupo y definir la propia identidad en términos de los atributos personales en lugar de las identificaciones del grupo. (p. 598)

industrial-organizational (I/O) psychology/psicología industrial y organizacional aplicación de conceptos y métodos psicológicos para optimizar el comportamiento humano en los lugares de trabajo. (pp. 14, 828)

inferential statistics/estadística inferencial datos numéricos que permiten generalizar, es decir, inferir a partir de una muestra de datos la probabilidad de que algo sea verdadero para una población. (p. 60)

informational social influence/influencia social informativa influencia resultante de la disposición de una persona para aceptar la opinión de los otros acerca de la realidad. (p. 764)

informed consent/consentimiento informado un principio ético que obliga a proporcionar a los participantes de una investigación los datos necesarios para que puedan decidir si efectivamente desean participar. (p. 68)

ingroup/endogrupo “nosotros”: personas con las que tenemos una identidad en común. (p. 784)

ingroup bias/favoritismo del endogrupo tendencia a favorecer al grupo al que pertenecemos. (p. 784)

inner ear/oído interno parte más profunda de la oreja; contiene la cóclea, los canales semicirculares y el vestíbulo. (p. 195)

insight/sagacidad comprensión súbita de la solución a un problema; contrasta con las soluciones basadas en estrategias. (pp. 297, 361)

insight therapies/terapias psicodinámicas variedad de terapias que tienen el propósito de mejorar el funcionamiento psicológico aumentando el nivel de conciencia que tiene una persona de sus motivos y defensas subyacentes. (p. 711)

insomnia/insomnio problemas recurrentes para dormir o quedarse dormido. (p. 238)

instinct/instinto comportamiento complejo que está arraigado y es innato en cada especie. (p. 391)

intellectual disability/discapacidad intelectual cuadro de capacidad mental limitada marcada por un cociente intelectual de 70 o menos, y por la dificultad de adaptarse a las exigencias de la vida. (Anteriormente se conocía como *retraso mental*). (p. 629)

intelligence/inteligencia calidad mental que consiste en la habilidad de aprender de la experiencia, resolver problemas y utilizar el conocimiento para adaptarse a nuevas situaciones. (p. 607)

intelligence quotient (IQ)/cociente intelectual (CI) definido originalmente como la proporción entre la edad mental (*em*) y edad cronológica (*ec*) multiplicada por 100 (por ende, $CI = ed/ec \times 100$). En las pruebas de inteligencia contemporáneas, al desempeño promedio de cada grupo etario se le asigna una puntuación de 100 y las puntuaciones correspondientes al desempeño relativo son mayores o menores que ese promedio. (p. 618)

intelligence test/prueba de inteligencia método para evaluar las aptitudes mentales de un individuo y compararlas con las de otros utilizando puntajes numéricos. (p. 607)

intensity/intensidad cantidad de energía en una onda luminosa o sonora que percibimos como brillo o intensidad sonora, determinada por la amplitud de la onda. (p. 172)

interaction/interacción acción que se ejerce recíprocamente cuando el efecto de un factor (como el ambiente) depende de otro factor (como la herencia). (p. 131)

internal locus of control/locus de control interno impresión de que controlamos nuestro propio destino. (p. 300)

interneurons/interneuronas neuronas del cerebro y la médula espinal que se comunican internamente e intervienen entre la estimulación sensorial y las respuestas motoras. (p. 87)

interpretation/interpretación en psicoanálisis, las observaciones del analista con relación al supuesto significado de los sueños, las resistencias, y otros comportamientos y eventos significativos, a fin de promover la sagacidad. (p. 710)

intimacy/intimidad en la teoría de Erikson, la habilidad de formar relaciones íntimas, amorosas. Una de las tareas principales del desarrollo de la adolescencia tardía y la adultez temprana. (p. 521)

intrinsic motivation/motivación intrínseca deseo de expresar un comportamiento eficazmente por el comportamiento en sí. (p. 297)

intuition/intuición sensación o pensamiento no esforzado, inmediato y automático, que contrasta con el razonamiento explícito y consciente. (p. 363)

iris/iris anillo de tejido muscular que forma la porción coloreada del ojo alrededor de la pupila y controla el tamaño de la apertura de la pupila. (p. 172)

James-Lange theory/teoría de James-Lange teoría que postula que nuestra experiencia emocional es nuestra conciencia de nuestras respuestas fisiológicas a los estímulos que despiertan nuestras emociones. (p. 421)

just-world phenomenon/hipótesis del “mundo justo” tendencia a creer que el mundo es justo y que las personas consiguen lo que se merecen y se merecen lo que consiguen. (p. 784)

kinesthesia/cinética sistema que siente la posición y el movimiento de las partes individuales de cuerpo. (p. 209)

language/lenguaje palabras habladas, escritas o en señas y las maneras en que las combinamos para comunicar significado. (p. 372)

latent content/contenido latente según Freud, el significado subyacente de un sueño (distinto de su contenido manifiesto). (p. 241)

latent learning/aprendizaje latente aprendizaje que ocurre pero que no es aparente hasta que surge un incentivo para demostrarlo. (p. 297)

law of effect/ley de efecto principio de Thorndike según el cual los comportamientos seguidos de consecuencias favorables se vuelven más probables y los comportamientos seguidos de consecuencias desfavorables se vuelven menos probables. (p. 275)

learned helplessness/indefensión aprendida indefensión y resignación pasiva que un animal o un ser humano desarrollan cuando son incapaces de evitar repetidos eventos de aversión. (p. 299)

learning/aprendizaje proceso de adquirir información o comportamientos nuevos y relativamente permanentes. (p. 263)

lens/lente estructura transparente detrás de la pupila que cambia de forma para ayudar a enfocar las imágenes en la retina. (p. 172)

lesion/lesión destrucción del tejido. Una lesión cerebral es una destrucción del tejido cerebral ya sea por efectos naturales o experimentales. (p. 94)

levels of analysis/niveles de análisis las distintas opiniones complementarias desde las biológicas, pasando por las psicológicas, hasta las socio-culturales, para analizar cualquier fenómeno. (p. 11)

limbic system/sistema límbico sistema neuronal (que incluye el *hipocampo*, la *amígdala* y el *hipotálamo*) ubicado debajo de los hemisferios cerebrales; está asociado con las emociones y los instintos. (p. 98)

linguistic determinism/determinismo lingüístico hipótesis de Whorf según la cual el lenguaje determina la manera que pensamos. (p. 379)

lobotomy/lobotomía procedimiento psiquirúrgico que se utilizó en una época para calmar a pacientes violentos o que padecían de emociones incontrolables. Mediante este procedimiento se separaba la conexión entre los lóbulos frontales y los centros de control de las emociones en las partes interiores del cerebro. (p. 746)

longitudinal study/estudio longitudinal investigación en la que las mismas personas son estudiadas y reexaminadas por un tiempo largo. (p. 543)

long-term memory/memoria a largo plazo tipo de memoria relativamente permanente e ilimitada. Incluye el conocimiento, las habilidades y las experiencias. (p. 319)

long-term potentiation (LTP)/potenciación a largo plazo (PLP) aumento en la eficiencia de una célula con estimulaciones breves y rápidas. Se cree que esta es la base neuronal para el aprendizaje y la memoria. (p. 333)

LSD/LSD droga alucinógena poderosa; también conocido como ácido (*dietilamida del ácido lisérgico*). (p. 254)

lymphocytes/linfocitos los dos tipos de glóbulos blancos que forman parte del sistema inmunológico: *los linfocitos del tipo B* se forman en la médula ósea y liberan anticuerpos que combaten las infecciones bacterianas; *los linfocitos del tipo T* se forman en el timo y en otro tejido linfático y atacan las células cancerosas, los virus y las sustancias extrañas. (p. 448)

major depressive disorder/trastorno depresivo mayor trastorno del estado de ánimo en el cual una persona (sin una condición médica y sin el uso de drogas) presenta cinco o más síntomas por un período mínimo de dos semanas; al menos uno de esos síntomas debe ser (1) depresión o (2) falta de interés o placer. (p. 672)

mania/manía trastorno del estado de ánimo marcado por una condición hiperactiva y desenfrenadamente optimista. (p. 673)

manifest content/contenido manifiesto según Freud, recuerdo de los eventos del sueño (distinto de su contenido latente u oculto). (p. 241)

maturation/maduración procesos biológicos de crecimiento que permiten los cambios estructurados en el comportamiento y que no están relativamente influenciados por la experiencia. (p. 471)

mean/media promedio aritmético de una distribución obtenidos sumando todos los puntajes y dividiendo el total por el número de puntajes. (p. 57)

median/mediana punto medio en una distribución; la mitad de los puntajes están por encima y la mitad están por debajo de la mediana. (p. 57)

medical model/modelo médico concepto que sostiene que las enfermedades (en este caso, los trastornos psíquicos) tienen causas físicas que pueden *diagnosticarse, tratarse* y, en la mayoría de los casos, *curarse*, por lo general mediante un tratamiento en un *hospital*. (p. 653)

medulla/médula base del tronco encefálico; controla el latido del corazón y la respiración. (p. 97)

memory/memoria el aprender de manera persistente a través del tiempo mediante la codificación, el almacenaje y la recuperación de la información. (p. 318)

menarche/menarquía primer período menstrual. (p. 527)

menopause/menopausia período en que la menstruación desaparece de manera natural; también se refiere a los cambios biológicos que una mujer experimenta al declinar su capacidad reproductora. (p. 540)

mental age/edad mental medida de desempeño en pruebas de inteligencia diseñada por Bidet. La edad cronológica normalmente corresponde a un nivel dado de desempeño. Por ende, una criatura que se desempeña como una persona normal de 8 años, tiene una edad mental de 8 años. (p. 618)

mental set/predisposición mental tendencia a tratar de resolver un problema de una manera en particular que, usualmente, ya ha funcionado en el pasado. (p. 362)

mere exposure effect/efecto de la mera exposición fenómeno que sostiene que la exposición repetida a estímulos novedosos aumenta su atracción. (p. 798)

meta-analysis/metaanálisis procedimiento para combinar estadísticamente los resultados de distintos estudios de investigación. (p. 731)

methamphetamine/metanfetamina droga poderosamente adictiva que estimula el sistema nervioso central con funciones corporales aceleradas y cambios de energía y estado de ánimo. Aparentemente, con el tiempo reduce los niveles mínimos de dopamina. (p. 253)

middle ear/oído medio cámara entre el tímpano y cóclea que contiene tres huesos diminutos (martillo, yunque y estribo) que concentran las vibraciones del tímpano en la ventana ovalada de la cóclea. (p. 195)

Minnesota Multiphasic Personality Inventory (MMPI)/Inventario multifásico de personalidad de Minesota (MMPI, por sus siglas en inglés) la prueba de personalidad más investigada y clínicamente utilizada. Esta prueba, originalmente desarrollada para identificar trastornos emocionales (todavía se considera que este es su uso más apropiado), hoy en día se utiliza con muchos otros propósitos. (p. 578)

mirror neurons/neuronas espejo neuronas del lóbulo frontal que, según algunos científicos, descargan impulsos cuando se realizan determinadas acciones o cuando se observa a otro hacerlas. Este proceso cerebral de reflejar las acciones de otro puede posibilitar la imitación y la empatía. (p. 304)

mirror-image perceptions/percepciones especulares opiniones mutuas que generalmente mantienen los individuos con sentimientos encontrados, por ejemplo, cuando uno de ellos se considera ético y pacífico y percibe al otro como malvado y agresivo. (p. 812)

misinformation effect/efecto de desinformación el incorporar información engañosa en nuestros recuerdos de un evento. (p. 347)

mnemonics/mnemónica ayudas de memoria, sobre todo esas técnicas que utilizan imágenes vívidas y dispositivos organizacionales. (p. 323)

mode/moda el puntaje o puntajes que ocurren con mayor frecuencia en una distribución. (p. 57)

modeling/modelado proceso de observar e imitar un comportamiento específico. (p. 304)

molecular genetics/genética molecular división de la biología que estudia la estructura molecular y la función de los genes. (p. 129)

monocular cues/indicaciones monoculares señales de profundidad como la interposición y la perspectiva lineal, que pueden ser extraídas de las imágenes de cada uno de los ojos. (p. 185)

mood disorders/trastornos del estado de ánimo trastornos psicológicos caracterizados por estados extremos de ánimo. Véase *trastorno depresivo mayor, manía y trastorno bipolar*. (p. 671)

mood-congruent memory/memoria congruente con el humor tendencia a recordar las experiencias que son consistentes con nuestro humor actual, bueno o malo. (p. 337)

morpheme/morfema en el lenguaje, la unidad más pequeña de significado; puede ser una palabra o parte de una palabra (como un prefijo). (p. 373)

motivation/motivación necesidad o deseo que da energía y dirige el comportamiento. (p. 390)

motor (efferent) neurons/neuronas motrices (eferentes) neuronas que transmiten la información del cerebro y la médula espinal hacia los músculos y las glándulas. (p. 86)

motor cortex/corteza motriz área en la parte posterior de los lóbulos frontales que controla los movimientos voluntarios. (p. 105)

MRI (magnetic resonance imaging)/IRM (imágenes por resonancia magnética) técnica que utiliza campos magnéticos y ondas de radio para producir imágenes de tejidos blandos generadas por computadora. Las IRM permiten observar la anatomía cerebral. (p. 95)

mutation/mutación error aleatorio en la réplica de los genes que tiene como resultado un cambio. (p. 136)

myelin sheath/vaina de mielina capa de tejido graso que encasilla los axones de algunas neuronas, facilitando una mayor velocidad de transmisión, ya que los impulsos neuronales saltan de un nódulo al siguiente. (p. 78)

narcissism/narcisismo autoestima exagerada y egotismo. (p. 597)

narcolepsy/narcolepsia trastorno del sueño caracterizado por ataques de somnolencia irresistibles con el sueño REM ocurriendo al inicio del sueño, a menudo en momentos inoportunos. (p. 238)

natural selection/selección natural principio según el cual, entre la variedad de rasgos heredados, aquellos que contribuyen a la reproducción y la supervivencia tienen gran probabilidad de pasar a las generaciones futuras. (pp. 10, 135)

naturalistic observation/observación naturalista el observar y registrar la conducta en situaciones reales sin tratar de manipular y controlar la situación. (p. 40)

nature-nurture issue/relación entre herencia y crianza larga controversia sobre las contribuciones relativas de los genes y la experiencia en el desarrollo de los rasgos psicológicos y las conductas. La ciencia actual considera que los rasgos y las conductas surgen de la interacción entre la naturaleza y la crianza. (p. 9)

near-death experience/experiencia al borde de la muerte estado de alteración experimentado por personas que llegan al borde de la muerte (por ejemplo, a causa de un paro cardíaco). Son similares a las alucinaciones inducidas por las drogas. (p. 255)

negative reinforcement/refuerzo negativo aumento de conductas como consecuencia de la omisión o reducción de un estímulo

negativo. Aquí se *omite* un estímulo después de una respuesta, y como consecuencia se refuerza dicha respuesta. (*Nota:* El refuerzo negativo no es castigo). (p. 278)

nerves/nervios conjunto de axones que forman “cables” neurales que conectan el sistema nervioso central con los músculos, las glándulas y los órganos de los sentidos. (p. 86)

nervous system/sistema nervioso veloz red electroquímica de comunicación del cuerpo que consiste de todas las células nerviosas del sistema periférico y del sistema nervioso central. (p. 86)

neurogenesis/neurogénesis formación de nuevas neuronas. (p. 112)

neuron/neurona célula nerviosa; el componente básico del sistema nervioso. (p. 78)

neurotransmitters/neurotransmisores mensajeros químicos que atraviesan los espacios intersinápticos entre las neuronas. Cuando son liberados por una neurona emisora, los neurotransmisores pasan a través de la sinapsis y se acomodan en los receptores de la neurona receptora, influyendo en la generación de un impulso neural por parte de dicha neurona. (p. 80)

neutral stimulus (NS)/estímulo neutro (EN) en el condicionamiento clásico, estímulo que no provoca respuesta antes del condicionamiento. (p. 266)

nicotine/nicotina droga psicoactiva estimulante y altamente adictiva que se encuentra en el tabaco. (p. 250)

night terrors/terrores nocturnos trastorno del sueño caracterizado por una gran excitación y la apariencia de estar aterrizado; a diferencia de las pesadillas, los terrores nocturnos ocurren durante el sueño NREM-3, dos o tres horas después de dormirse, y raramente se recuerdan. (p. 239)

norm/norma regla entendida de comportamiento aceptado y esperado. Las normas prescriben el comportamiento “apropiado”. (p. 777)

normal curve/curva normal (*distribución normal*) curva simétrica en forma de campana que describe la distribución de muchos tipos de datos. La mayoría de los puntajes están cerca de la media (aproximadamente el 68 por ciento están dentro de una desviación estándar de esta) y disminuyen en número conforme se acercan a los extremos. (pp. 59, 621)

normative social influence/influencia social normativa influencia que resulta del deseo de una persona de ganar la aprobación o evitar la desaprobación. (p. 764)

NREM sleep/sueño de NREM (por sus siglas en inglés) sueño en el que no hay un movimiento ocular rápido; abarca todas las etapas del sueño, salvo la REM. (p. 228)

object permanence/permanencia de objeto conocimiento de que las cosas existen aunque no las percibamos. (p. 478)

observational learning/aprendizaje observacional el aprender observando a otros. (También se lo conoce como *aprendizaje social*). (p. 304)

obsessive-compulsive disorder (OCD)/trastorno obsesivo-compulsivo (TOC) trastorno caracterizado por pensamientos (obsesiones) o acciones (compulsiones) que son repetitivos y no deseados. (p. 663)

occipital lobes/lóbulos occipitales porción de la corteza cerebral ubicada en la parte posterior de la cabeza; incluye las áreas que reciben información de los campos visuales. (p. 105)

Oedipus complex/complejo de Edipo según Freud, los deseos sexuales de un muchacho hacia su madre y sentimientos de celos y odio para el padre rival. (p. 559)

one-word stage/etapa holofrástica etapa en el desarrollo del habla en la que el niño, de entre 1 y 2 años, se expresa principalmente con palabras aisladas. (p. 375)

operant behavior/comportamiento operante comportamiento que opera en el ambiente, produciendo consecuencias. (p. 289)

operant chamber/cámara operante en los estudios del condicionamiento operante, cámara (también conocida como *caja de Skinner*) equipada con una barra o llave que un animal manipula para obtener un reforzador de comida o agua; unos dispositivos llevan un registro de las veces en que el animal aprieta la barra o picotea la llave. (p. 276)

operant conditioning/condicionamiento operante aprendizaje donde el comportamiento se consolida si está seguido por un refuerzo o se atenúa si está seguido por un castigo. (p. 275)

operational definition/definición operacional manifestación cuidadosamente redactada de los procedimientos exactos (operaciones) utilizados en una investigación. Por ejemplo, la *inteligencia humana* puede ser operacionalmente definida como lo que mide una prueba de inteligencia. (p. 39)

opiates/opiatas el opio y sus derivados, tales como la morfina y la heroína; deprimen la actividad neuronal, disminuyendo el dolor y la ansiedad temporalmente. (p. 250)

opponent-process theory/teoría de los procesos opuestos teoría según la cual los procesos opuestos en la retina (rojo-verde, amarillo-azul, blanco-negro) permiten la visión de colores. Por ejemplo, algunas células son estimuladas por el verde e inhibidas por el rojo; otras son estimuladas por el rojo e inhibidas por el verde. (p. 179)

optic nerve/nervio óptico nervio que transporta los impulsos neuronales del ojo al cerebro. (p. 173)

organizational psychology/psicología organizacional subdivisión de la psicología industrial y organizacional que examina las influencias organizacionales en la satisfacción y productividad de los trabajadores, y facilita los cambios organizacionales. (p. 828)

other-race effect/efecto de otras razas tendencia a recordar con mayor precisión los rostros de individuos de la raza a la cual uno pertenece que los rostros de individuos de otras razas. (También se denomina *efecto interracial*). (p. 786)

outgroup/exogrupo “ellos”: personas que consideramos distintas o ajenas a nuestro endogrupo. (p. 784)

overconfidence/confianza excesiva tendencia a estar más seguros de nosotros mismos que a estar en lo cierto, o sea, de sobreestimar la exactitud de nuestras creencias y opiniones. (p. 365)

panic disorder/trastorno de pánico trastorno de ansiedad marcado por episodios impredecibles de aprehensión intensa que pueden durar varios minutos. Incluyen dolor de pecho, sofocamiento y otras sensaciones atemorizantes. Estos episodios suelen ir seguidos del temor por un posible ataque futuro. (p. 662)

parallel processing/procesamiento paralelo procesamiento simultáneo de varias partes de un problema; el modo natural del cerebro de procesar la información de muchas funciones, incluida la visión. Contrasta con el procesamiento paso a paso (en serie) de la mayoría de las computadoras y de la resolución consciente de problemas. (pp. 176, 319)

parapsychology/parapsicología estudio de fenómenos paranormales incluyendo la percepción extrasensorial y la psicoquinesis. (p. 167)

parasympathetic nervous system/sistema nervioso autonómico parasimpático división del sistema nervioso autonómico que calma el cuerpo conservando su energía. (p. 87)

parietal lobes/lóbulos parietales área de la corteza cerebral en la parte superior y hacia la parte posterior de la cabeza que recibe suministro sensorial para el tacto y la posición del cuerpo. (p. 105)

partial (intermittent) reinforcement/refuerzo parcial (intermitente) refuerzo a una respuesta solo parte del tiempo; tiene como resultado la adquisición más lenta de una respuesta pero mucho más resistente a la extinción que el refuerzo continuo. (p. 279)

passionate love/amor apasionado estado excitado de intensa y positiva absorción en otro ser, normalmente presente al comienzo de una relación amorosa. (p. 803)

perception/percepción proceso de organizar e interpretar la información sensorial, permitiéndonos reconocer los objetos y eventos significativos. (p. 152)

perceptual adaptation/adaptación visual habilidad de acomodarnos a un campo visual artificialmente desplazado o hasta invertido. (p. 191)

perceptual constancy/constancia perceptiva percepción de los objetos como inalterables (de forma, tamaño, luminosidad y color constantes) aunque cambien la iluminación y las imágenes en la retina. (p. 186)

perceptual set/predisposición perceptiva predisposición mental para percibir una cosa y no otra. (p. 163)

peripheral nervous system (PNS)/sistema nervioso periférico (SNP) neuronas sensoriales y motrices que conectan el sistema nervioso central (SNC) al resto del cuerpo. (p. 86)

peripheral route persuasion/persuasión por ruta periférica se observa cuando los individuos son influenciados por claves secundarias, por ejemplo, el atractivo físico de un orador. (p. 756)

personality/personalidad forma característica de pensar, sentir y actuar de un individuo. (p. 555)

personality disorders/trastornos de la personalidad trastornos psicológicos caracterizados por modelos de comportamiento inflexibles y duraderos que impiden el funcionamiento social. (p. 698)

personality inventory/inventario de personalidad cuestionario (a menudo con preguntas de *verdadero/falso*, *estoy de acuerdo/estoy en desacuerdo*) diseñado para medir un amplio rango de sentimientos y comportamientos, utilizados para evaluar ciertos rasgos de personalidad. (p. 578)

personality psychology/psicología de personalidad estudio de la forma característica de pensar, sentir y actuar de un individuo. (p. 14)

personnel psychology/psicología de personal subdivisión de la psicología industrial y organizacional que está enfocada en el reclutamiento, selección, colocación, entrenamiento, evaluación y desarrollo de los empleados. (p. 828)

PET (positron emission tomography)/TEP (tomografía por emisión de positrones) presentación gráfica de la actividad cerebral que detecta por dónde pasa una fórmula radiactiva de glucosa mientras el cerebro realiza una tarea determinada. (p. 95)

phi phenomenon/fenómeno phi ilusión de movimiento creado cuando dos o más luces adyacentes destellan en sucesión rápida. (p. 185)

phobia/fobia trastorno de ansiedad marcado por un temor persistente e irracional y la evasión de un objeto, actividad o situación específicos. (p. 662)

phoneme/fonema en el lenguaje, la unidad de sonido más pequeña. (p. 373)

pitch/tono lo agudo o grave de un sonido. Esta característica depende de la frecuencia. (p. 195)

pituitary gland/glándula pituitaria glándula más influyente del sistema endocrino. Bajo la influencia del hipotálamo, la pituitaria regula el crecimiento y controla otras glándulas endocrinas. (p. 91)

place theory/teoría de ubicación en la audición, la teoría que relaciona al tono que oímos con el lugar donde la membrana de la cóclea se estimula. (p. 199)

placebo effect/efecto de placebo [del latín, "complaceré"] resultados experimentales causados exclusivamente por expectativas; cualquier efecto en el comportamiento causado por el suministro de una sustancia o condición inerte que el sujeto del experimento considera agente activo. (p. 52)

plasticity/plasticidad capacidad del cerebro de cambiar, especialmente durante la niñez, reorganizándose después de sufrir una lesión o formando nuevas conexiones a partir de las experiencias del individuo. (p. 111)

polygraph/polígrafo máquina, usualmente utilizada para intentar detectar mentiras, que mide varias de las respuestas fisiológicas que acompañan la emoción (tales como la transpiración y los cambios cardiovasculares y de respiración). (p. 428)

population/población todos los individuos del grupo estudiado de los que se pueden tomar muestras. (*Nota:* a excepción de los estudios nacionales, esto no se refiere a la población entera de un país). (p. 43)

positive psychology/psicología positiva estudio científico del funcionamiento humano cuyas metas consisten en descubrir y promover las fuerzas y las virtudes que permiten prosperar a individuos y comunidades. (pp. 15, 590)

positive reinforcement/refuerzo positivo el aumentar la probabilidad de una conducta con el uso de refuerzos positivos. Un refuerzo positivo es cualquier estímulo que, *presentado* después de una respuesta, la fortalece. (p. 277)

posthypnotic suggestion/sugestión poshipnótica sugestión hecha durante una sesión de hipnosis, para que el sujeto la cumpla cuando ya no esté hipnotizado; técnica empleada por algunos médicos clínicos para tratar de controlar conductas y síntomas indeseados. (p. 220)

post-traumatic growth/evolución post-traumática cambios psicológicos positivos que resultan de la lucha por superar circunstancias extremadamente difíciles y crisis de vida. (p. 665)

post-traumatic stress disorder (PTSD)/trastorno de estrés post-traumático (TEPT) trastorno caracterizado por recuerdos obsesivos, pesadillas, aislamiento social, ansiedad asustadiza, insensibilidad o insomnio que dura por cuatro semanas o más después de una experiencia traumática. (p. 664)

predictive validity/validez predictiva éxito con cuál una prueba predice el comportamiento que está diseñada para predecir; se evalúa computando la correlación entre los puntajes de la prueba y el criterio de comportamiento. (También se la denomina *validez de criterio*). (pp. 345, 622)

prejudice/prejuicio *actitud* injustificable y normalmente negativa hacia un grupo y sus miembros. El prejuicio generalmente implica creencias estereotipadas, sentimientos negativos y una predisposición a acción discriminatoria. (p. 780)

preoperational stage/etapa preoperacional en la teoría de Piaget, la etapa (desde los 2 hasta los 6 o 7 años de edad, aproximadamente) durante la que el niño aprende a utilizar el lenguaje; pero todavía no comprende las operaciones mentales de lógica concreta. (p. 479)

primary reinforcer/refuerzo primario estímulo natural de refuerzo, como cuando uno satisface una necesidad biológica. (p. 278)

primary sex characteristics/características sexuales primarias estructuras del cuerpo (ovarios, testículos y genitales externos) que hacen posible la reproducción sexual. (p. 527)

priming/exposición previa activación normalmente inconsciente de ciertas asociaciones mentales que predispone la percepción, la memoria o la respuesta de un individuo. (pp. 157, 336)

proactive interference/interferencia proactiva efecto de interferencia cuando el material que ha sido aprendido anteriormente dificulta recordar la información nueva. (p. 345)

problem-focused coping/resolución enfocada en el problema intento por aliviar la tensión directamente, ya sea cambiando estresor o la manera como interactuamos con este. (p. 298)

projective test/prueba de proyección prueba de personalidad, como la de Rorschach, que proporciona estímulos ambiguos diseñados para activar la proyección de nuestra dinámica interna. (p. 567)

prosocial behavior/comportamiento prosocial comportamiento positivo, constructivo, útil. Lo contrario del comportamiento antisocial. (p. 307)

prototype/prototipo imagen mental o mejor ejemplo de una categoría. La comparación de elementos nuevos con un prototipo proporciona un método rápido y fácil de clasificar por categorías (como al comparar animales de plumas con un prototipo de ave, como el ruiseñor). (p. 356)

psychiatry/psiquiatría división de la medicina que trata con trastornos psicológicos; practicado por médicos que a veces proporcionan tratamientos médicos (por ejemplo, con drogas) así como terapia psicológica. (p. 15)

psychoactive drug/droga psicoactiva sustancia química que altera las percepciones y el humor. (p. 246)

psychoanalysis/psicoanálisis (1) teoría de la personalidad de Sigmund Freud que atribuye los pensamientos y acciones a motivos y conflictos inconscientes; técnicas utilizadas para tratar trastornos psicológicos exponiendo e interpretando las tensiones inconscientes. (p. 557) (2) la técnica terapéutica de Freud. Freud creía que las asociaciones libres, las resistencias, los sueños y la transferencia del paciente—y las interpretaciones del terapeuta sobre ellos—liberaban los sentimientos previamente reprimidos, permitiendo al paciente ganar introspección. (p. 709)

psychodynamic psychology/psicología psicodinámica rama de la psicología que estudia cómo los impulsos y conflictos inconscientes influyen en el comportamiento, y utiliza esa información para tratar a quienes tienen trastornos psicológicos (p. 12)

psychodynamic theories/teorías psicodinámicas enfoques actuales que analizan la personalidad concentrándose en el inconsciente y en la importancia de las experiencias de la niñez. (p. 565)

psychodynamic therapy/terapia psicodinámica (1) terapia derivada de la tradición psicoanalítica, en la que se considera que las personas responden a fuerzas inconscientes y a experiencias de la niñez, y que tiene el propósito de aumentar el conocimiento de uno mismo. (p. 710)

psychological disorder/trastorno psicológico síndrome marcado por una alteración clínicamente significativa de la cognición, la regulación de las emociones o la conducta de un individuo. (Adaptado de la Asociación psiquiátrica estadounidense, 2013). (p. 651)

psychology/psicología estudio científico del comportamiento y de los procesos mentales. (p. 7)

psychometrics/psicometría el estudio científico de la medida de las capacidades, las actitudes y los rasgos humanos. (p. 13)

psychoneuroimmunology/psiconeuroinmunología estudio del efecto de los procesos psicológicos, neurales y endocrinos en el sistema de inmunidad y la salud resultante. (p. 448)

psychopharmacology/psicofarmacología estudio de los efectos de las drogas en la mente y el comportamiento. (p. 740)

psychophysics/psicofísica estudio de las relaciones entre las características físicas de los estímulos, como su intensidad, y nuestra experiencia psicológica de ellos. (p. 155)

psychophysiological illness/enfermedad psicofisiológica término que significa literalmente enfermedad “de la mente y el cuerpo”; cualquier enfermedad física que tenga relación con el estrés, por ejemplo, la hipertensión y ciertos dolores de cabeza. (p. 448)

psychosexual stages/etapas psicosexuales etapas del desarrollo infantil (oral, anal, fálica, latente, genital) durante las cuales, según Freud, la energía del id en busca de placer se enfoca en zonas erógenas específicas. (p. 559)

psychosis/psicosis trastorno psicológico debido al cual la persona pierde contacto con la realidad, dando lugar a ideas irracionales y percepciones distorsionadas. (p. 684)

psychosurgery/psicocirugía cirugía que remueve o destruye tejido cerebral para cambiar el comportamiento. (p. 746)

psychotherapy/psicoterapia tratamiento en el que se emplean técnicas psicológicas; consiste en interacciones entre un terapeuta especializado y una persona que desea superar dificultades psicológicas o lograr una evolución personal. (p. 709)

puberty/pubertad período de maduración sexual durante el cual una persona adquiere la capacidad de reproducirse. (p. 527)

punishment/castigo evento que tiende a *disminuir* el comportamiento que le precede. (p. 281)

pupil/pupila apertura adaptable en el centro del ojo a través del cual la luz ingresa. (p. 172)

random assignment/asignación aleatoria distribución al azar de participantes a grupos experimentales y de control para minimizar las diferencias preexistentes entre los diferentes grupos. (p. 51)

random sample/muestra aleatoria muestra que representa fielmente a una población porque cada elemento tiene igual oportunidad de ser seleccionado. (p. 43)

range/rango diferencia entre el puntaje más alto y el más bajo en una distribución. (p. 58)

rational-emotive behavior therapy (REBT)/terapia racional emotiva conductual (TREC) terapia cognitiva de confrontación

formulada por Albert Ellis que desafía con énfasis las actitudes y suposiciones ilógicas y de autoderrota de las personas. (p. 721)

recall/recuerdo medida de la memoria en la que la persona debe recuperar información aprendida con anterioridad, como en las pruebas donde se debe llenar el espacio en blanco. (p. 334)

reciprocal determinism/determinismo recíproco interacción de las influencias de conducta, cognición interna y entorno. (p. 588)

reciprocity norm/norma de reciprocidad expectativa de que las personas ayudarán y no herirán a aquellos que las han ayudado. (p. 809)

recognition/reconocimiento medida de la memoria en la que la persona solo debe identificar los artículos previamente aprendidos, como en una prueba de selección múltiple. (p. 334)

reflex/reflejo reacción simple y automática a un estímulo sensorial, como el reflejo de la rodilla. (p. 89)

refractory period/periodo refractario (1) período de inactividad neuronal posterior a la descarga de un impulso. (p. 79) (2) período de descanso después de un orgasmo durante el cual el hombre no puede tener otro orgasmo. (p. 407)

regression toward the mean/regresión hacia la media la tendencia que tienen los puntajes extremos o inusuales de revertirse (regresar) hacia el promedio. (p. 730)

reinforcement/refuerzo en el condicionamiento operante, cualquier evento que *fortalece* la conducta que le precede. (p. 276)

reinforcement schedule/programa de refuerzo patrón que define la frecuencia con la que se reforzará una respuesta deseada. (p. 279)

relative deprivation/privación relativa percepción de que uno está peor relativamente que aquellos a los que uno se compara. (p. 851)

relearning/reaprendizaje medida de memoria que evalúa la cantidad de tiempo ahorrado cuando se aprende el material la segunda vez. (p. 334)

reliability/fiabilidad medida en la que una prueba produce resultados parejos que son evaluados por la uniformidad de puntajes en dos partes de la prueba, en diferentes versiones de esta, o bien al administrarla nuevamente. (p. 622)

REM rebound/rebote de REM la tendencia a un aumento marcado del sueño REM como consecuencia de la privación del sueño REM (producida por despertares repetidos durante el sueño REM). (p. 243)

REM sleep/sueño REM (por sus siglas en inglés) sueño con movimiento ocular rápido; etapa recurrente en el sueño durante la cual ocurren sueños vívidos. También se conoce como *sueño paradójico* porque los músculos están relajados (excepto por pequeños espasmos); pero el resto de los sistemas corporales se mantienen activos. (p. 226)

repetitive transcranial magnetic stimulation (rTMS)/estimulación magnética transcraneal repetitiva (EMTr) aplicación repetitiva de pulsos de energía magnética al cerebro; utilizada para estimular o suprimir la actividad cerebral. (p. 745)

replication/replicación el repetir la esencia de un estudio de investigación, usualmente con diferentes participantes y en diferentes situaciones, para ver si las conclusiones básicas se extienden a otros participantes y circunstancias. (p. 39)

representativeness heuristic/heurística de la representatividad estrategia para estimar la probabilidad de un suceso mediante la

evaluación de su parecido o concordancia con ciertos prototipos; a veces conduce a ignorar otros datos relevantes. (p. 364)

repression/represión en la teoría psicoanalítica, el mecanismo básico de defensa por medio del cual el sujeto elimina de su consciente aquellos pensamientos, emociones o recuerdos que le producen ansiedad. (pp. 346, 560)

resilience/capacidad de recuperación la fuerza personal que ayuda a la mayoría de las personas a superar el estrés y recuperarse de la adversidad e incluso de los traumas. (p. 737)

resistance/resistencia en psicoanálisis, el bloquear del consciente aquello que está cargado de ansiedad. (p. 710)

respondent behavior/conducta respondiente conducta que ocurre como respuesta automática a un estímulo. (p. 289)

reticular formation/formación reticular red de nervios que atraviesa el tronco encefálico y el tálamo, y que juega un papel importante en el control de la excitación. (p. 98)

retina/retina superficie sensitiva a la luz en la parte interior del ojo que contiene los receptores de luz llamados bastoncillos y conos además de capas de neuronas que inician el procesamiento de la información visual. (p. 172)

retinal disparity/disparidad retiniana clave binocular en la percepción de profundidad. El cerebro calcula distancias comparando las imágenes reflejadas en la retina de cada ojo. Cuanto más grande es la disparidad (diferencia) entre las dos imágenes, más cerca está el objeto. (p. 184)

retrieval/recuperación proceso de sacar la información que está almacenada en la memoria. (p. 319)

retroactive interference/interferencia retroactiva efecto de interferencia cuando el material que ha sido aprendido recientemente dificulta recordar lo aprendido con anterioridad. (p. 345)

retrograde amnesia/amnesia retrógrada incapacidad de recuperar información sobre el propio pasado. (p. 342)

reuptake/reabsorción reabsorción de un neurotransmisor por la neurona emisora. (p. 80)

rods/bastoncillos receptores de la retina que detectan el negro, el blanco y el gris; necesarios para la visión periférica y en la penumbra, cuando los conos no responden. (p. 173)

role/rol conjunto de expectativas (normas) relacionadas a una posición social, definiendo como aquellos en esa posición deben comportarse. (pp. 503, 758)

Rorschach inkblot test/test de Rorschach la prueba proyectiva más utilizada, que consiste en un conjunto de 10 manchas de tinta, diseñado por Hermann Rorschach; busca identificar los sentimientos internos de las personas analizando sus interpretaciones de las manchas. (p. 567)

rumination/rumiación preocupación compulsiva; *pensar demasiado* en nuestros problemas y sus causas. (p. 679)

sampling bias/sesgo de muestreo proceso de toma de muestras defectuoso que da como resultado una muestra no representativa. (p. 43)

savant syndrome/síndrome de savant condición según la cual una persona de habilidad mental limitada tiene una destreza excepcional en un campo específico como la computación o el dibujo. (p. 609)

scapegoat theory/teoría del chivo expiatorio teoría que propone que el prejuicio ofrece un escape para la cólera porque nos brinda a alguien a quien culpar. (p. 785)

scatterplot/diagramas de dispersión agrupaciones de puntos en una gráfica, cada una de las cuales representa el valor de dos variables. La pendiente de los puntos representa la dirección de la relación entre las dos variables. La magnitud de la dispersión representa la fuerza de la correlación (a menor dispersión, mayor correlación). (p. 46)

schema/esquema concepto o principio que organiza e interpreta la información. (p. 477)

schizophrenia/esquizofrenia trastorno psicológico caracterizado por delirios, alucinaciones, discurso desorganizado o expresiones emocionales insuficientes o inapropiadas. (p. 684)

secondary sex characteristics/características sexuales secundarias características sexuales no reproductivas, como senos y caderas en las mujeres, timbre de voz y vello corporal en los hombres. (p. 527)

selective attention/atención selectiva enfoque de la percepción consciente en un estímulo en particular. (p. 152)

self/el yo en la psicología contemporánea, supuesto centro de la personalidad, organizador de nuestros pensamientos, sentimientos y acciones. (p. 594)

self-actualization/autorrealización según Maslow, una de las necesidades psicológicas fundamentales que surge después de satisfacer las necesidades básicas, físicas y psicológicas, y de lograr la autoestima; motivación de satisfacer nuestro potencial. (p. 571)

self-concept/autoconcepto todos nuestros pensamientos y sentimientos hacia nosotros mismos cuando respondemos a la pregunta: "¿quién soy yo?" (pp. 492, 572)

self-control/autocontrol capacidad de controlar los impulsos y posponer la gratificación a corto plazo a cambio de mayores recompensas a largo plazo. (p. 301)

self-disclosure/autorrevelación el revelar aspectos íntimos de uno mismo a otros. (p. 804)

self-efficacy/autoeficacia percepción que tenemos de nuestra competencia y eficacia. (p. 595)

self-esteem/autoestima sentimiento valorativo positivo o negativo de nuestro ser. (p. 595)

self-fulfilling prophecy/profecía autocumplida creencia que lleva a su propio cumplimiento. (p. 812)

self-serving bias/sesgo de autoservicio tendencia a auto-percibirse de manera favorable. (p. 596)

sensation/sensación proceso por el cual los receptores sensoriales y el sistema nervioso reciben y representan el estímulo del medio ambiente. (p. 152)

sensorimotor stage/etapa sensorio-motriz en la teoría de Piaget, la etapa (desde el nacimiento hasta aproximadamente los 2 años de edad) durante la que los infantes conocen el mundo principalmente en términos de sus impresiones sensoriales y actividades motoras. (p. 478)

sensorineural hearing loss/pérdida sensorio-neuronal del oído pérdida auditiva causada por daño a las células receptoras de la cóclea o a los nervios auditivos. (También se la denomina *sordera del nervio*). (p. 197)

sensory (afferent) neurons/neuronas sensoriales (aférentes) neuronas que transportan al cerebro y a la médula espinal la información proveniente de los receptores sensoriales. (p. 86)

sensory adaptation/adaptación sensorial sensibilidad disminuida como consecuencia del estímulo constante. (p. 159)

sensory interaction/interacción sensorial principio que un sentido puede influir a otro, como cuando el aroma de la comida influye en su sabor. (p. 210)

sensory memory/memoria sensorial registro muy breve e inmediato de la información sensorial en el sistema de la memoria. (p. 319)

serial position effect/efecto de posición serial nuestra tendencia a recordar mejor los últimos y los primeros artículos en una lista (*efectos de recencia y de primacía*, respectivamente). (p. 337)

set point/punto fijo punto de equilibrio en el "termostato del peso" de un individuo. Cuando el cuerpo llega a un peso debajo de este punto, se produce un aumento en el hambre y una disminución en el índice metabólico, los cuales pueden actuar para restablecer el peso perdido. (p. 398)

sexual dysfunction/disfunción sexual problema que impide la excitación o el funcionamiento sexual. (p. 407)

sexual orientation/orientación sexual atracción sexual perdurable hacia los miembros del mismo sexo (orientación homosexual), del sexo opuesto (orientación heterosexual) o de ambos (orientación bisexual). (p. 531)

sexual response cycle/ciclo de respuesta sexual las cuatro etapas de respuesta sexual descritas por Masters y Johnson: excitación, meseta, orgasmo y resolución. (p. 406)

shallow processing/procesamiento superficial codificación básica originada en la estructura o el aspecto de las palabras. (p. 324)

shaping/modelado por aproximaciones sucesivas procedimiento del condicionamiento operante donde los refuerzos guían la conducta para que esta se aproxime más y más a la conducta deseada. (p. 276)

short-term memory/memoria a corto plazo memoria activada que retiene algunos elementos por un corto tiempo, tales como los siete dígitos de un número telefónico mientras se marca, antes que la información se almacene o se olvide. (p. 319)

signal detection theory/teoría de la detección de señales teoría que predice cómo y cuándo detectamos la presencia de un estímulo débil (*señal*) a pesar de la estimulación del ambiente (*ruido*). Asume que no hay ningún umbral absoluto y que la detección depende en parte de la experiencia de la persona, de sus expectativas, motivación, y vigilancia. (p. 156)

skewed distribution/distribución asimétrica representación de puntajes que no guardan simetría respecto del valor promedio. (p. 58)

sleep/sueño pérdida del conocimiento que es periódica y natural. Esto es distinto de la inconsciencia que puede resultar del estado de coma, anestesia general, o hibernación. (Adaptado de Dement, 1999). (p. 227)

sleep apnea/apnea del sueño trastorno de sueño caracterizado por cesaciones temporales de respiración durante el sueño y repetidos despertares momentáneos. (p. 239)

social anxiety disorder/trastorno de ansiedad social temor intenso a situaciones sociales que lleva a evitarlas. (Anteriormente se denominaba *fobia social*). (p. 662)

social clock/reloj social manera que la sociedad tiene de marcar el tiempo adecuado de los eventos sociales, tales como matrimonio, paternidad y jubilación. (p. 544)

social exchange theory/teoría del intercambio social teoría que establece que nuestra conducta social es un proceso de intercambio, cuyo objetivo es maximizar los beneficios y minimizar los costos. (p. 809)

social facilitation/facilitación social mejor desempeño en las tareas simples o bien aprendidas en la presencia de otros. (p. 771)

social identity/identidad social dentro de nuestro autoconcepto, parte a la que nos referimos como “nosotros”; la parte de nuestra respuesta a la pregunta “¿quién soy yo?” que tiene que ver con nuestras afiliaciones de grupo. (p. 519)

social leadership/liderazgo social liderazgo orientado hacia el grupo que construye trabajo en grupo, media en el conflicto y ofrece apoyo. (p. 838)

social learning theory/teoría de aprendizaje social teoría que establece que aprendemos la conducta social observando e imitando, y al ser recompensados o castigados. (p. 504)

social loafing/haraganería social tendencia de las personas en un grupo de realizar menos esfuerzo cuando juntan sus esfuerzos para lograr una meta común que cuando son responsables individualmente. (p. 773)

social psychology/psicología social estudio científico de los pensamientos, las influencias y las relaciones que hay entre las personas. (pp. 14, 754)

social script/guión social guía que establece cómo debe actuarse en diversas situaciones en una cultura determinada. (p. 792)

social trap/trampa social situación en la cual las partes en conflicto, cada una persiguiendo racionalmente su propio interés en lugar del bien del grupo, se ven atrapadas en una conducta mutuamente destructiva. (p. 810)

social-cognitive perspective/perspectiva cognitivo-social enfoque según el cual la conducta es influenciada por la interacción entre los rasgos del individuo (incluida la forma de pensar) y su contexto social. (p. 587)

social-cultural psychology/psicología social-cultural el estudio de cómo situaciones y culturas afectan nuestra conducta y pensamiento. (p. 12)

social-responsibility norm/norma de responsabilidad social posibilidad de que las personas ayudarán a quienes las necesiten. (p. 810)

somatic nervous system/sistema nervioso somático división del sistema nervioso periférico que controla los músculos del esqueleto. (También se lo conoce como *sistema nervioso del esqueleto*). (p. 87)

somatic symptom disorder/trastorno de síntoma somático trastorno psicológico en el que los síntomas cobran carácter somático (del cuerpo) sin tener una causa física aparente. (Véase *trastorno de conversión y trastorno de ansiedad por enfermedad*). (p. 693)

somatosensory cortex/corteza somatosensorial area en la parte frontal de los lóbulos parietales que registra y procesa las sensaciones corporales de tacto y movimiento. (p. 107)

source amnesia/amnesia de la fuente el atribuir un origen erróneo a un evento que hemos experimentado, oído, leído o imaginado. (También se le conoce como *falsa atribución*). La amnesia de la fuente, así como el efecto de desinformación, es la causa de muchos recuerdos falsos. (p. 349)

spacing effect/efecto del aprendizaje espaciado tendencia a que el estudio o práctica distribuidos logren mejor retención a largo plazo que la que se logra a través de estudio o prácticas masivas. (p. 324)

split brain/cerebro dividido estado a partir de una intervención quirúrgica en el que los dos hemisferios cerebrales quedan comunicados mediante el corte de las fibras que los conectan (principalmente las del cuerpo calloso). (p. 114)

spontaneous recovery/recuperación espontánea reaparición, después de una pausa, de una respuesta condicionada extinguida. (p. 269)

spotlight effect/efecto reflector sobreestimación de lo que los demás advierten y evalúan de nuestra apariencia, desempeño y desatinos (como si estuviéramos apuntados por un reflector). (p. 594)

SQ3R/método EPL2R técnica de estudio que combina cinco pasos: explorar, preguntar, leer, recitar y repasar. (p. 16)

standard deviation/desviación estándar medida calculada de cuánto varían los puntajes alrededor del promedio de la muestra. (p. 58)

standardization/estandarización el definir procedimientos uniformes de evaluación y puntajes significativos mediante la comparación del desempeño de un grupo examinado con anterioridad. (p. 621)

Stanford-Binet/Stanford-Binet revisión estadounidense (por Terman en la Universidad de Stanford) de la prueba original de inteligencia de Binet. Esta prueba revisada es usada extensamente. (p. 618)

statistical significance/significado estadístico declaración estadística de cuán probable es que un resultado se haya obtenido por casualidad. (p. 60)

stereotype/estereotipo creencia (a veces acertada, pero frecuentemente demasiado generalizada) sobre las características de un grupo de personas. (p. 780)

stereotype threat/amenaza del estereotipo preocupación personal que reconfirma el temor de ser evaluado sobre una base de un estereotipo negativo. (p. 642)

stimulants/estimulantes drogas —como la cafeína, la nicotina y las anfetaminas más poderosas (cocaína, éxtasis y metanfetamina)— que excitan la actividad neuronal y aceleran las funciones corporales. (p. 250)

stimulus/estímulo cualquier evento o situación que provoque una respuesta. (p. 264)

storage/almacenamiento proceso de retener información codificada a través del tiempo. (p. 319)

stranger anxiety/miedo a los extraños temor a los extraños que los infantes normalmente expresan a partir de los 8 meses, aproximadamente. (p. 488)

stress/estrés proceso a través del cual percibimos y respondemos a ciertos eventos llamados *estresores*, los cuales evaluamos como amenazantes o desafiantes. (p. 442)

structuralism/estructuralismo escuela de los primeros años de la psicología, promovida por Wundt y Titchener, que empleaba la introspección para explorar la estructura de la mente humana. (p. 4)

structured interviews/entrevistas estructuradas proceso mediante el cual en las entrevistas se hace las mismas preguntas a todos los postulantes, cada uno de los cuales será calificado de acuerdo a escalas establecidas. (p. 832)

subjective well-being/bienestar subjetivo percepción de felicidad o satisfacción con la vida. Se utiliza con las medidas de bienes-

tar objetivo (por ejemplo, los indicadores físicos y económicos) para evaluar la calidad de vida de las personas. (p. 847)

subliminal/subliminal debajo del umbral absoluto del nivel de conciencia. (p. 157)

substance use disorder/trastorno por uso de sustancias deseo y uso continuo de una sustancia a pesar del deterioro de la calidad de vida o el riesgo físico. (p. 246)

superego/superego parte de personalidad que, según Freud, representa los ideales interiorizados y provee de las normas para el juicio (la conciencia) y para las aspiraciones futuras. (p. 558)

superordinate goals/metras comunes metas compartidas que hacen caso omiso de las diferencias entre las personas y que requieren su cooperación. (p. 813)

suprachiasmatic nucleus (SCN)/núcleo supraquiasmático (NSQ) dos grupos de células ubicados en el hipotálamo que controlan el ritmo circadiano. El NSQ es el responsable de que la epífisis ajuste la producción de melatonina en respuesta a la luz, alterando así nuestras sensaciones de somnolencia. (p. 229)

survey/encuesta técnica para verificar las actitudes o conductas reportadas por las personas; usualmente se pregunta a una muestra aleatoria y representativa. (p. 42)

sympathetic nervous system/sistema nervioso simpático división del sistema nervioso autónomo que en situaciones estresantes excita al cuerpo y moviliza su energía. (p. 87)

synapse/sinapsis intersección entre el extremo del axón de una neurona emisora y la dendrita o cuerpo celular de una neurona receptora. El pequeño espacio en esta intersección se denomina *espacio intersináptico*. (p. 80)

systematic desensitization/desensibilización sistemática tipo de terapia de exposición en la que se asocia un estado tranquilo y placentero con estímulos graduales que producen ansiedad. Se emplea comúnmente para tratar fobias. (p. 717)

task leadership/liderazgo específico liderazgo orientado a metas específicas que establece las normas, organiza el trabajo y centra la atención en las metas. (p. 838)

telegraphic speech/lenguaje telegráfico etapa en que un niño comienza a hablar expresándose en forma de telegrama (“dame” o “agua”) y utilizando principalmente sustantivos y verbos. (p. 375)

temperament/temperamento característica de reactividad emocional e intensidad de una persona. (p. 490)

temporal lobes/lóbulos temporales porción de la corteza cerebral ubicada aproximadamente arriba de las orejas; incluye las áreas auditivas, cada una de las cuales recibe la información auditiva principalmente de la oreja opuesta. (p. 105)

tend and befriend/cuidar y hacer amistades en situaciones estresantes, la gente (especialmente las mujeres) suele acercarse a otras personas para ofrecer su apoyo (cuidar), generar vínculos y buscar respaldo (hacer amistades). (p. 445)

teratogens/teratógenos (literalmente, “fabricantes de monstruos”) agentes, como las sustancias químicas o los virus, que pueden afectar al embrión o al feto durante el desarrollo prenatal y causarle daño. (p. 467)

terror-management theory/teoría de la gestión del terror teoría sobre la ansiedad relacionada con la muerte; explora las respuestas emocionales y conductuales de las personas a todo aquello que les haga recordar la muerte propia. (p. 568)

testing effect/efecto del test incremento de la memoria tras recuperar la información, en vez de limitarse a releerla. En ocasiones se lo denomina efecto de *práctica de recuperación de la información o aprendizaje por evaluación*. (pp. 16, 324)

testosterone/testosterona la más importante de las hormonas sexuales masculinas. Tanto los hombres como las mujeres la tienen, pero la testosterona adicional en los hombres estimula el crecimiento de los órganos sexuales masculinos en el feto y el desarrollo de las características sexuales masculinas durante la pubertad. (pp. 408, 526)

thalamus/tálamo estructura cerebral ubicada sobre el tronco encefálico que funciona como centro de control para dirigir información a las áreas sensoriales receptivas de la corteza cerebral y transmite respuestas al cerebelo y la médula. (p. 97)

THC/THC principal sustancia activa encontrada en la marihuana; produce distintos efectos incluyendo alucinaciones leves. (p. 255)

Thematic Apperception Test (TAT)/prueba de apercepción temática (PAT) prueba psicológica proyectiva en la que las personas expresan sus sentimientos internos e intereses a través de historias que inventan a partir de escenas ambiguas. (p. 567)

theory/teoría explicación que utiliza un conjunto integrado de principios que organiza las observaciones y predice los comportamientos o eventos. (p. 38)

theory of mind/teoría de la mente ideas de la gente con relación a su estado de ánimo y al estado de ánimo de los demás: sus sentimientos, percepciones y pensamientos, y la conducta que estos puedan predecir. (p. 480)

therapeutic alliance/alianza terapéutica vínculo de confianza y comprensión mutua que se forma entre el terapeuta y el cliente para trabajar juntos de manera constructiva y lograr superar el problema de este último. (p. 735)

threshold/umbral nivel de estímulo requerido para activar un impulso neuronal. (p. 80)

token economy/economía de fichas procedimiento del condicionamiento operante en el cual las personas ganan fichas de algún tipo si exhiben una conducta deseada y luego pueden cambiar las fichas por privilegios o regalos. (p. 719)

tolerance/tolerancia efecto decreciente de la misma dosis de una droga después de un tiempo de uso, requiriendo que el usuario aumente la dosis para poder experimentar el efecto de la droga. (p. 246)

top-down processing/procesamiento de arriba a abajo procesamiento de información dirigida por procesos mentales superiores, como cuando determinamos nuestras percepciones a partir de nuestra experiencia y nuestras expectativas. (p. 152)

trait/rasgo patrón característico de conducta o una disposición para sentir y actuar, tal como los reportaría una autoevaluación o evaluación por nuestros pares. (p. 576)

transduction/transducción cualquier operación que transforma energía de determinado tipo en otro distinto. En el caso de los sistemas sensoriales, el transformar energía de estímulo, como visiones, sonidos y olores, en impulsos neuronales que nuestros cerebros son capaces de interpretar. (p. 155)

transference/transferencia en el psicoanálisis, la transferencia de emociones ligadas a otras relaciones, del paciente al analista (como el amor u odio hacia uno de los padres). (p. 710)

transgender/transexual término abarcador que describe a aquellas personas cuya identidad o expresión sexual difiere de la asociada con el sexo con el que nacieron. (p. 505)

two-factor theory/teoría bifactorial teoría de Schachter y Singer que sostiene que para sentir una emoción, la persona debe (1) experimentar estimulación física y (2) clasificar la estimulación a nivel cognitivo. (p. 422)

two-word stage/etapa de dos palabras a partir de los 2 años, etapa del desarrollo del lenguaje durante la cual el niño emite mayormente frases de dos palabras. (p. 375)

Type A/Tipo A término de Friedman y Rosenman para las personas competitivas, compulsivas, impacientes, verbalmente agresivas y con tendencia a enojarse. (p. 452)

Type B/Tipo B término de Friedman y Rosenman para las personas tolerantes y relajadas. (p. 452)

unconditional positive regard/consideración positiva incondicional según Carl Rogers, actitud que no juzga, bondadosa y sin restricciones que ayuda a los clientes a desarrollar la conciencia y a aceptarse a sí mismos. (pp. 572, 712)

unconditioned response (UR)/respuesta incondicionada (RI) en el condicionamiento clásico, la respuesta no aprendida e innata (como la salivación) que es producida por un estímulo incondicionado (EI) (como la comida en la boca). (p. 267)

unconditioned stimulus (US)/estímulo incondicionado (EI) en el condicionamiento clásico, un estímulo no condicionado -natural y automático- que produce una respuesta (RI). (p. 267)

unconscious/inconciente según Freud, un depósito de pensamientos, deseos, sentimientos y recuerdos en su mayoría inaceptables. Según los psicólogos contemporáneos, el procesamiento de información del cual no estamos alertas. (p. 557)

validity/validez grado en que una prueba mide o predice lo que se supone que debe medir o predecir (véase también *validez de contenido y validez predictiva*). (pp. 53, 622)

variable-interval schedule/programa de intervalo variable en el condicionamiento operante, un programa de refuerzo que refuerza una respuesta después de intervalos de tiempo impredecibles. (p. 280)

variable-ratio schedule/programa de razón variable en el condicionamiento operante, un programa de refuerzo que refuerza una respuesta después de un número impredecible de respuestas. (p. 280)

vestibular sense/sentido vestibular sentido de movimiento del cuerpo y posición, incluyendo el sentido de equilibrio. (p. 209)

virtual reality exposure therapy/terapia de exposición a una realidad virtual tratamiento de ansiedad que progresivamente expone a las personas a simulaciones de sus más grandes miedos, como los vuelos en avión, las arañas o hablar en público. (p. 718)

visual cliff/precipicio visual dispositivo del laboratorio para examinar la percepción de profundidad en los infantes y animales jóvenes. (p. 184)

wavelength/longitud de onda distancia de la cresta de una onda luminosa o sonora a la cresta de la próxima. Las longitudes de onda electromagnéticas varían desde los puntos de luz cortos de los rayos cósmicos hasta los pulsos largos de transmisión de radio. (p. 171)

Weber's law/ley de Weber principio que, para que dos estímulos sean percibidos como diferentes, estos deben variar en un porcentaje mínimo constante (en vez de en una cantidad constante). (p. 158)

Wechsler Adult Intelligence Scale (WAIS)/escala de la Inteligencia de Wechsler para adultos (EIWA) la prueba de inteligencia más ampliamente utilizada; contiene evaluaciones verbales y de desempeño (no verbales). (p. 620)

Wernicke's area/área de Wernicke controla la recepción del lenguaje. Un área del cerebro involucrada en la comprensión y la expresión del lenguaje; generalmente en el lóbulo temporal izquierdo. (p. 377)

withdrawal/síndrome de abstinencia incomodidad y angustia que ocurren luego de descontinuar una droga o comportamiento adictivos. (p. 247)

working memory/memoria activa aproximación nueva a la memoria a corto plazo que involucra el procesamiento consciente y activo de la información auditiva y visual-espacial, además de la recuperación de información de la memoria a largo plazo. (p. 320)

X chromosome/cromosoma X cromosoma del sexo encontrado en hombres y mujeres. Las mujeres tienen dos cromosomas X; los hombres tienen uno. Un cromosoma de X de cada progenitor produce una niña. (p. 526)

Y chromosome/cromosoma Y cromosoma del sexo encontrado solo en los hombres. Cuando se aparea con un cromosoma X de la madre, produce un niño. (p. 526)

Yerkes-Dodson law/ley de Yerkes-Dodson principio según el cual el desempeño mejora con la excitación solo hasta cierto punto; luego, comienza a decaer. (p. 392)

Young-Helmholtz trichromatic (three-color) theory/teoría tricromática (tricolor) de Young-Helmholtz teoría que establece que la retina contiene tres tipos de receptores cromáticos —uno más sensible al rojo, otro al verde, otro al azul— que, cuando se estimulan simultáneamente, pueden producir la percepción de cualquier color. (p. 178)

zygote/cigoto huevo fertilizado, que atraviesa por un período de 2 semanas de división celular rápida y se convierte en un embrión. (p. 466)

The Story of Psychology: A Timeline (continued from inside front cover)

- 1949**— In *The Organization of Behavior: A Neuropsychological Theory*, Canadian psychologist Donald O. Hebb outlines a new and influential conceptualization of how the nervous system functions.
- 1950**— Solomon Asch publishes studies of effects of conformity on judgments of line length.
- 1951**— In *Childhood and Society*, Erik Erikson outlines his stages of psychosocial development.
- 1951**— Carl Rogers publishes *Client-Centered Therapy*.
- 1952**— The American Psychiatric Association publishes the *Diagnostic and Statistical Manual of Mental Disorders*, an influential book that will be updated periodically.
- 1953**— Eugene Aserinski and Nathaniel Kleitman describe rapid eye movements (REM) that occur during sleep.
- 1954**— Janet Taylor's Manifest Anxiety Scale appears in the *Journal of Abnormal Psychology*.
- 1954**— In *Motivation and Personality*, Abraham Maslow proposes a hierarchy of motives ranging from physiological needs to self-actualization. (Maslow later updates the hierarchy to include self-transcendence needs.)
- 1954**— James Olds and Peter Milner, McGill University neuropsychologists, describe rewarding effects of electrical stimulation of the hypothalamus in rats.
- 1954**— Gordon Allport publishes *The Nature of Prejudice*.
- 1956**— In his *Psychological Review* article titled "The Magical Number Seven, Plus or Minus Two: Some Limits on Our Capacity for Processing Information," George Miller coins the term *chunk* for memory researchers.
- 1957**— Robert Sears, Eleanor Maccoby, and Harry Levin publish *Patterns of Child Rearing*.
- 1957**— Charles Ferster and B. F. Skinner publish *Schedules of Reinforcement*.
- 1959**— Noam Chomsky's critical review of B. F. Skinner's *Verbal Behavior* appears in the journal *Language*.
- 1959**— Eleanor Gibson and Richard Walk report their research on infants' depth perception in "The Visual Cliff."
- 1959**— Harry Harlow outlines "The Nature of Love," his work on attachment in monkeys.
- 1959**— Lloyd Peterson and Margaret Peterson in the *Journal of Experimental Psychology* article, "Short-Term Retention of Individual Verbal Items," highlight the importance of rehearsal in memory.
- 1959**— John Thibaut and Harold Kelley publish *The Social Psychology of Groups*.
- 1969**— In his APA presidential address, "Psychology as a Means of Promoting Human Welfare," George Miller emphasizes the importance of "giving psychology away."
- 1971**— Kenneth B. Clark becomes the first African-American president of the American Psychological Association.
- 1971**— Albert Bandura publishes *Social Learning Theory*.
- 1971**— Allan Paivio publishes *Imagery and Verbal Processes*.
- 1971**— B. F. Skinner publishes *Beyond Freedom and Dignity*.
